What? You couldn't disagree, so you had to pick on my spelling? Pretty lame.. Of course, you caught the one thing I expected you would, when I put it in there.. I guess homosexuals CAN be anal retentive.

Just my two cents.

==========
Tim now you are talking out your ass, why would you need a rms meter to peak
a radio? explain, ...use a peak meter and tune it for the highest peak
unless something changed last night in electronics this will yield your
highest going forward rms watts as well

The largest carrier the radio will do which still yields a forward swing, I would think...

I have a 2-2290 driving 4-2879's This is a X- Force that I am trying to repair and need some info. Awhile back the I smoked the last two caps that tune the output to the antenna. The problem is I pulled the bad parts out a couple of months ago and cant find them, and don't remember the values. There is a silver mica and a metal cap that goes between the combiner and the relay. If any one has this amp and can at a glance tell me what those values are I would immensely appreciate it. I would rather put what was originally in there back in then experiment with different value caps, I just want to replace it and be done with it.

I wouldn't worry too much about a dipole being directional. Unless
it is higher than 1/2 wave length above ground, it has an
omni-directional
pattern. The pattern also depends on surrounding objects
(distortion).

Bill:

Thanks for the input on this one, too... Another big question, though....

How could I test field strength without a field strength meter? I don't have access to one that's worth a darn. I suppose I could get one of the cheapies from RatShack, but I'd really like to do this right... Is there a way to test field strength without said meter?

I know its a strech, but, well, I'm of limited means, which is one of the reasons I'm building my own antenna, rather than buying one.

Thx, and 73

> > Bill Nelson (billn@peak.org)
> >

Take these definitions from a former driver:

Chicken Coop: Weigh station
Pickle Park: Rest area
City Kitty: Local cop.
County Mountie: County cop.
Smokey Bear: State cop.
Full Grown: DMV/ Motor Carrier Enforcement. (State cop with the BIG ticket book)

Yardstick: Mile Marker.
Brake Check: Major slowdown ahead.
10-4, 4-10, 42 = OK... Interchangeable.
10-33 = accident someplace, usually followed by the mile marker
10-36 = what time is it?
Radio check = Obvious... usually followed by, "Check's in the mail" or "It's workin" or "I got mine, where's yours?"

These are the basics. There's others of course...

HTH.

Is your mic cord green? If not, it's been replaced, and you'll just have to use
a continuity tester to figure out which pin does what.

Sorry I couldn't be more helpful.

Dave:

Good deal. I need to know what wires connect to what pins on the key switch in there. Mine is completely rotted out, and I need to totally reconstruct it.

I REALLY appreciate this, Dave. I want to bring this mic back to life. They're great mic's, when they're working.

There will be absolutely no difference in radiating efficiency whether
the same antenna is fed with 1500 watts, or 100 milliwatts.

Rule of thumb without meters to set your mike...
Every power mike I've ever run I set about 1/3 or 3 out of 10 with my radio's mike gain full open. You can also look at the meter on the radio and say "audio", set the mike where it just wiggles the meter at 6" from your mout, doesn't move at all at 12", and then at 2" will give you good response without picking up wind noise like you're in a hurricane.

I think I used (Or rather positive I used the wrong term. I did say "nice feedback". I forgot what I was saying and to whom. I should have said "I am getting nice response", not thinking the actual to feedback being radio/signal related. My error.

I AM, however going to take Terry's (pencilpusher) suggestion and haul it off the Jeep.

I am so looking forward to learning this area. I already know everything else. LOL I've always been fascinated by radios et al. After a while, after I become more versed in the ways of the "radio", I'd like to get a much better system. Perhaps even VHF or HF. I like seeing the personalized plates beginning with VE3XXX.

Thanks again,
JP

Same as the 148GTL, Grant XL, and 2000.

You'll need a couple extra parts. Some good quality hook-up wire, a 1K Pot, and a knob.

1. Jumper R187. (remove and replace with a piece of wire)
2. Remove R188.
3. Remove D75, D52 and R44
4. Remove orange wire (attached to clarifier) from board, solder to center lead of 1K pot. Right hand lead from 1K pot gets a piece of wire soldered to it. Other end goes to pin 3 of IC4
5. Remove green wire (attached to clarifier. Might be white, too) from board. Solder to hole closest to VR5 where D75 used to be. You may have to follow the trace from the center leg of VR5 to find the right hole.
6. Remove blue wire (attached to clarifier) from board. Attach to hole where R44 used to be closest to D51.
7. Drill a hole and mount the 1K pot in an accessible place, and attach the knob. This is your fine tuner.
8. Center fine tuner knob and clarifier knob.
9. Realign radio so that it is on frequency. The main problem here is with USB, so I suggest you tune that first. If you "bottom out" the tuning coil for USB, and it's still not on freq, use VR5 to center it up. Then align AM and LSB.

This will give 6Kc each way on the clarifier, and 400 cycles each way on the fine tuner. The circuit is stable, as well, because of (I've been told.) the extra distributed capacitance in the 1K pot and VR5.

If you want more slide than this, jumper D51 as well.

HTH.

tuning with a field strength meter is much too much trouble for
this old man.... its hard to run fast enough to the back yard
to see the meter befor the carrier drops out <grin>
just hang the thing and feed it with 50 or 75 ohm coax, trim
to a low swr and start talking. don't worry about it. that
will give you ulsers....

Source record: 48230

shouldn't be hard to figure out...even with out an ohm meter.

open up the original mic plug and look at it. the shield will
go to the same number pin and the wire that the shield is wraped
around (usually white, red or yellow) will go to the same pin..

the other two wires you have a 50/50 chance. if the radio keys
up as soon as the mic is pluged in then reverse them.

with the turner +2 white is your audio red is transmit and black
is the rcve wire. and of course the shield is ground.

.....I hope you mean #12 wire (AWG)... even that would be excessive at
only 200 watts... #18-20 AWG would suffice, but may not survive a severe
windstorm.

<sideband asked>
> >4. If I build it, for example, 1/4 wave each side, is that a 1/2 wave
> >dipole, or a 1/4 wave dipole?

<Brad replied >
> this would be a half wave dipole which has more gain the 1/4 wave dipole
> does

.....a 1/2 wave dipole is considered to be 'unity' gain... ZERO gain. It
is the standard against which most other antennas are compared for purposes
of measuring gain. A 1/4 wave dipole?.... now THAT would present an
interesting feedpoint impedance to match!

1768. Home-brew helical wire length

Newsgroup: rec.radio.cb
Date: 2000-08-15 00:00:00 UTC
From: Cory Papenfuss <papenfus@juneau.ece.uiuc.edu>
Message-ID: <4scm5.889$9N1.15284@vixen.cso.uiuc.edu>
Source record: 48235

OK... now this has been bugging me. For the past few days, I've
been trying to build a 1/4 wave continuously-loded dipole, but cannot for
the life of me get it to match at 27 MHz. The fiberglass rod I've been
using is 3/8" by 6' long and I've tried a number of different lengths
wound around it. Since I've got access to a network analyzer, I've used
it to check the impedance through a frequency sweep from 1-100MHz so I can
see all the resonant points. If I use a straight piece of wire about 104"
long, the impedance looks good (40 +-j5 or so) at 27MHz. As soon as I try
to put the wire on the rod, the resonance changes. Now while I expect
this from the additional inductance from the coiling, it appears to make
it impossible to get the number of turns correct. As I put more wire on,
the spacing gets closer together and the two cancel each other out for
resonance elsewhere than 27 MHz. Is there some magical length the rod
should be (other than 6') for this to work? I've seen advertisements for
5/8 wave, 3/4 wave, and 1/4 wave continuously loaded dipoles.... what
gives? Also, I've noticed an affinity for largely-space coils towards the
bottom and tighter-space towards the top. Is there a good reason for this
from a raditation resistance perspective?
Sorry about the ramblings, but just figured I'd give the whole
story so people won't waste there time suggesting stuff I've tried
already.

Thanks,
-Cory

it shows your not thinking much. you can easily take a radio and make it backswing but on a pep meter it will still show forward modulation. thats the whole point i was making as why these johnny come lately techs need rms meters too because they dont have the skill to convert one reading to another in there heads.

>The largest carrier the radio will do which still yields a forward swing, I

My name is David and I am the sales manager of the largest Export Radio site on the net. One of my hobbies is to talk on and about radios. I've always enjoyed tinkering with radios and like to give advise on how to fix common problems. One of my good friends is a technician at my company and has helped design radios for some of the major manufactures of exports. I'm always asking him stupid questions and he is always giving me in depth answers. He has taught me a lot about radios, but I still want to learn more. If you have a technical question, I would enjoy trying to help you with it. If I can't give an answer, it will just give me a chance to make my tech friend think real hard. I've tried this on other forums and the response was great. Also, if you have some advise about a technical issue, post it. Maybe someone can learn from you also.

David

You really want the antenna tuned (unless you have an antenna tuner or transmatch) - a high SWR could possibly hurt your radio (read fry the finals). If you have an antenna tuner, however, the antenna does not have to be resonant. It could even be a half wave end fed (which is not as dependant upon a good ground. If you have an antenna tuner, just pull that 10 foot whip out to 9 feet and run a half wave - you'd have a heck of a signal. Just do it ONLY with a good antenna tuner - the radio wants to see a low SWR and you can do that with the tuner.

> shielding may help). Thanks.

Sounds like you may have some alternator noise, or depending on the
year of your vehicle, maybe fuel pump noise. But do this. Turn off
the
ANL, and disconnect the antenna. Do you still hear the noise? If so,
then it's coming in on the power lead. Do like the other posts say,
run a power lead to the battery, not the fuseblock. Fuse both (+) and
(-) leads, or at least the (+) lead (both is best). Connect a .470 mF
at 35-50 volt capacitor across the power leads as close to the radio
as
is practical. Did that reduce or eliminate the noise? If it
eliminated
the noise, good. If it reduced the noise, add another capacitor in
parallel with the first one.
Do the above and tell us what happened...
'Doc

There is not much differance tuning for lowest swr or field strength..Would
you rather have good gain and a 2.5 to 1 swr or slightly less gain and a
1.5 swr ... I prefer the lower swr It is much easier as hillbilly said ...

Tim what do i tell them i tell em knock thier soxs off a Cobra 29 will not swing a rms meter forward with a 10 watt dead key, a peak meter reads a dead carrier just the same as a rms only meter.. what is a dead key ? it is a rms reading ..Most every peak meter that i have ever seen also will read average/rms watts It is a good idea to use both while peaking a radio . In the end the person tuning has to know how many watts the radio is capable of and tune it accordingly. But to say you only need a rms meter is not correct

hi bill. never did i or would i say you need a peak reading or rms meter only.
you proved my point by what you said. a cobra 29 will not swing a rms forward
at 10 watts carrier your right, problem is it will swing a pep meter forward at
10 watts carrier and a person that doesnt know better will think everything is
ok because there seeing a forward swing still and will leave it set there. the
peak meters with the avg switch on them rarely work as true rms or pep meters.
there often a strange hybrid between.

The part about the mike gain is good.. I forgot about that.. experiment turning your mike gain up and the mike's volume down until you get the right combination.. I personally prefer to have the mike further away when I'm driving, even on my lap.. so I tend to have mine turned up a little more.. only thing is you'll get lots of background noise if it's noisy (Going down a highway or something..)

For using the car stereo for a "speaker" - it works, obviously, but I wouldn't bother with that.. I've done that before and I just found it go annoying after a short period - just a well placed speaker will do the trick.. if you have a PA jack, there's a talkback speaker you can get that plugs in the speaker and PA jacks, and allows you to have talkback without any modification of the radio - doesn't work on all radios (like the 2950), but does work on most...

1783. Q: Mounting an antenna

Newsgroup: rec.radio.cb
Date: 2000-08-15 00:00:00 UTC
From: TiggersBounce <ZJilla@HotMail.com>
Message-ID: <01c006dd$2cbb8600$9e14efd1@default>
Source record: 48300

I'm putting a fiberglass whip (probably a Silverload) on my Jeep. I want to mount it on the front fender near the AM/FM antenna, just to keep things clean. I was wondering though if there was such a thing as mounting them 'too close'. I was thinking 2-3" away, and using the factory bezels and such to make it look like an OE installation. I don't want to drill the hole, do the install and then find out I have a ton of interference. Any input regarding distance from other antennas would be appreciated.

When you swept the antenna for resonance points what was the lowest one you found? Normally you want the loading toward the middle and top, coils don't radiate very well so you want them away from the current nodes. Are you sure the rod is solid fiberglass. I had a wierd problem trying to build an antenna like yours and their was a wire inside what I thought was a fiberglass rod. This will screw things up royally. What you are trying to do is not that hard to do normally. I have gotten to the point where I must assume you are doing something wrong. What are you using for a ground plane when you test your antenna?

Since this is your first antenna and you have the right lab equipment i suggest you do a little experiment. Take the antenna yo have built with 104 inches of wire on it and measure its resonant frequecy. This should be the lowest frequecy at which it will resonate. Now make one up with half as much wire but also only use half of the fiberglass rod. This will give you an idea of how loading will effect the antenna. Btw , you did not tell us enough. If you swept the antenna why didn't you post the data, No one can help you if you keep what you are doing a secret and make us guess. Yes, you rambled but you didn't say a whole lot of anything.

Tim, not the meters i use ..a bird or coaxial meter meter with a peak reading function works well. as does diamond, yasue and a few other .. lets not talk dosy or dozy meters or radio shack ..the actual watt readings are basically irelavent if you are peaking a radio, you want to see an improvement from what you started with ..we can go on

> And did it significantly attenuate the cross channel modulation?

I've got it in my 2950 and it doesn't really effect adjacent channel bleed oever that much as far as I can tell. But it does make the receive in general much more quiet. a lot easier to understand weak signals.

>Thanks,

As I said before. It takes much more than 104 inches of wire on a
physically shortened antenna. For example, a KW7 Firestik has
265 inches of wire. A upper center loaded 6 foot Hustler has
about 138 inches of conductor. You need considerably more
than 104 inches of wire on a fiberglass form.

Coax length doesn't matter.

Tune SWR at your antenna, not with the coax.

i think exportradios.com has them .

is an antenna built different from any other out there .

it has about an 84 " whip . and i am 1:1 for about 3 bands , and don't go over 1.5 till i get so far off band you get into the 10 and 12 meter freq's

it claims a +6 dbi gain , and a 7/8 wave . either of these i don't belive .

but in every way it beats wilson , tx , rx , swr , and looks .

Your plan should be fine, if I read it right. The only interference a mobile CB might encounter would be noise from the ignition system, or bleedover from other CBers or strong local AM or FM signals (in rare instances)... and either way, your antenna mount would have very little to do with that.
Good luck-
Linus

1811. Re: How about some radio secrets!!

It should either be longer or shorter, but just to say that the swr is 2:1 at a given frequency doesn't provide enough information. Here is the baisics of antenna length: the higher the frequency, the shorter the antenna. If the antenna is most resonant on, say, channel 5, and the swr creeps up as you go on up to 40, then it is a bit too long.

If they don't care... they should.
Backswing indicates the wave is clipping and audio distortion will result.

I just stumbled across this group. Looks like there's alot of good info here. Maybe y'all can help me out a little.

I just installed a new radio in my pick up. Problem is the 18' coax I purchased is too short to reach the antenna (located on rear bumper). Can I get a coupler and another, say, 6' length of cable and splice the two? Or, am I better off having a longer cable made? I was told that 18' is the proper length, so I tried to make that work. I'm dealing with a Cobra 75 WXsomething or other, and a Cobra (I think) "High Gear" antenna.

Hello Hillbilly Dave: Oh yeah! Sounds like you have this a time or two or three.

Good advice, Dave.

I have done quit a bit of antenna field strength comparison testing, between different antennas. To see differences in a locally positioned field strength meter, and to correlate the measured field strength measurements vs antenna adjustments is very difficult at best, and very likely you are doing something wrong from such a close in field strength measurement. That can too easily be corrupted by ground reflections, reflections from near by objects, like you, tree's, buildings ect.

I have a guy down the road ah ways, about 1 mile away look at his S-meter, while measuring and comparing S-meter strengths with a 1 dB step (or increment) attenuator. Then many more field strength measurements are made and repeated to verify the measured comparisons are repeatable and correct. But also the different antennas are placed on the same mast, use the same coax, are at the same height, driven by the same radio, and after a few repeatable measurements, will I believe the comparison tests.

The difference from a perfect 1.0 to 1 SWR as compared to a 6 to 1 SWR is only approx. 3 dB. which is close to 1/2 to 1 S-unit on a typical CB Radio. I have the guy on the other end use a Kenwood TS(something) that has a calibrated S-meter, along with the 1 dB step Attenuator. This gives a pretty close Field Strength comparison measurement.

I agree with Bill Nelson on doing field strength measurements, but the field strength measurement procedure requires explanation, at the very least. It is not a simple thing to do accurately. Hillbilly Dave sounds to be a experienced hand, at this.

If your gonna tune a antenna, take notes, and document the SWR vs frequency on paper. Note how the antenna is installed, and the SWR on the different channels. Note what adjustments you have made, and what dimensions have been changed by how much length has changed. Take your time, and don't rush. NOTHING is made to work real quick in the electromagnetic world. Methodically documenting the antennas installation, SWR measurements, or field strength measurements, and later making simple graphs and charts will show you the way.

I wish I had a dime every time I had to go back and measure something, because I didn't write the test results down, at the 1st or 2nd time of taking them. Stupid Stupid Stupid.....

Cold beer to be issued only after antenna measurements are documented,
with antenna installation documented, and SWR charts colored in. Ok to
have Rock & Roll music in background, is ok.

1819. Re: Damn engine noise. Help!

Newsgroup: rec.radio.cb
Date: 2000-08-15 00:00:00 UTC
From: John Amero <" johnaNO§PAM"@island.net>
Message-ID: <3999C4A2.92F2B24C@island.net>
Source record: 48336

For those real tough power line noises
try the following...

POWER LINE NOISE FILTER
Note if the car is in need of a tune-up
this filter may not get rid of much of
the ignition noise.
Here is what you do. The filter I made
measures 5" long x 4" wide x 3" high.
Lets start with a rundown of parts:- 1-
2 electrolytic capacitors 6500 UF each
at 15 to 18 working volts.
If you can find one capacitor with
12000 to 20,000UF OK but you
may
need to adjust the size of filter box.
Get the Capacitors
first
because the size varies and will
determine the filter box
size.
my to capacitors measure 3.25" X 1"
diameter each. They
should
have a mounting bracket.

1- 1 ceramic disk.047 pf 100
V Cap.(capacitor),1 ceramic 5
pf 100v cap,
2- 1 ceramic 180 pf 100v Cap., 1 0.5
mf cap, 1 electrolytic 5mf 50v
Cap.
3- 1 1.2K Ohm 5 watt resistor
4- 1 0.5" to 0.75" ID ferrite core
5- 2 chassis mount SO-239 connectors
like the type the antenna hooks
on to the back of the CB.
6- 1 chassis mount fuse holder
7- 18 feet of #14 wire that is used
for winding electric motors...
"magnet-wire".
8- 5/8" X 5" (length of the filter
box) soft metal round bar.
9- 1 metal project box from Radio
Shack. 5" x 4" x 3"; wider if the

big capacitors are larger than I mentioned earlier
10- 12v relay like they use for fog lamps
11- 2 thick PVC or nylon washers, 1.5" in Diameter X 3/17" thick (May have to make)
12- 6" of thin 3/4" heat shrink you can get most of the stuff at Radio Shack or your favorite electronic surplus.

CONSTRUCTION
We need to make a choke out of the bar, motor wire, plastic washers and heat shrink. Cut the 5/8" bar so that it and the 2 washers fit snugley into the _length_ of the box. Drill and thread each end of the rod to take a 3/16" or #12 bolt. This is to secure the choke to each end of the box. Heat shrink the full length of the rod. Secure the plastic washers to each end of the rod. Grove one of the washers to allow the first winding to come to the top of the choke. If the washers are thick enough you can angle drill for the wire on a angle... this makes a neat exit. Now neatly, tightly and uniformly wind the wire on the rod and from washer to washer, do not overlap wire. You should get _about_ 3 layers. With a 1.5' lead out of the grooved or drilled washer and a 6" lead from the top layer tape or heat shrink the core in place, making sure that the windings _do not_ come loose. Drill the box for the screws in the rod and secure in the center, bottom of the box as close as to the bottom as the washers will let you. The core should be no less that 0.5" from the bottom.
Over the grooved washer install the SO-239 chassis mount connector; on one of the 4 screws place a solder tag. This is the_INPUT_ so mark it. Install the large capacitor(s)... they should have a mount. Install the other SO-239 chassis connector (at other end) with a solder tag to...off to one side leaving

room for the fuse holder to go next to it. REMEMBER YOU HAVE TO HAVE ROOM TO GET IN TO SOLDER LEADS AND LEAVE ROOM FOR THE LID AND SIDES SO THERE ARE NO SHORTS ETC.!
Using #12 automotive wire wind as many turns through the ferrite core as passable and connect one end to the center conductor of the input connector and the other to the choke lead. Trim leads for neatness. Connect the 5 watt resistor from the center conductor to the solder tag installed earlier. If you are using 2 large capacitors connect the positive post to the IN center conductor and the negative to the grounded solder tag. Use #16 automotive wire for jumpers. Solder in place. At the other end connect the choke lead to the center of the fuse holder lead, solder. connect a #14 jumper from the other fuse lead to the _OUT_ center conductor of the other SO-239 chassis mount connector. Also connect the other large capacitor positive lead to the center conductor and other to ground (the solder tag).To the center end (between the out center conductor or + lead) and fuse holder and connect the other end of the .024pf, 5pf, 180pf, .05mf and to ground; connect the 5mf electrolytes to the same way observing polarity. THIS FILTER IS FOR A NEGATIVE GROUND CAR IF POSITIVE REVERSE THE ELECTROLYTIC POLARITIES. Try to keep the wiring as short and neat as possible. To one of the screws of the choke attach about 14" of #10 auto wire using appropriate wire connectors. SOLDER ALL CRIMP ON CONNECTORS!

INSTALLING IN CAR
Using _#10_ auto wire run a lead directly from the battery to a spot where the lead from the filter to the CB will NOT be any longer than 2.5 feet. If you want the system to operate with the ignition key install the relay in a convent place. Attach the #10 wire attached to the choke screw to a GOOD car ground and use as short a lead as

possible. NOTE #10 wire is used not for the sake of amps but to reduce RF loops. Resistance is considerably higher at RF than DC.

CONNECTING CB TO FILTER
After the filter has been tested, we will connect the CB to the Filter. For wire we will use RG8/u Mini or better yet shielded #12 pair. Use as short as a length as possible an keep this run away from other wiring, especially parallel. Attach a PL 259 connector to one end of the RG8 and fix to filter output. If there is room in the back of the CB AND it does NOT disturb ANY wiring install a chassis mount SO-239 connector for the power in and mark RED well. If this is to difficult then run the RG8 power line to the last 1.5" of the power cord if it pugs into the back of the set, if the cord goes through the CB then connect and solder inside.

TIPS AND COMMENTS
I have used this in a Blazer, Caviler, and Dodge Neon, all have been kept tuned up. With out the filter I got some ignition noise and severe alternator and windshield wiper noise. All was stopped with this filter. I can't stress enough the importance of the neatness of ALL wiring and All automotive wiring other than the filter itself; use the proper connectors and terminals and solder ALL connections. Crimps only let in corrosion. Where there are bare wires that may short use heat shrink. The RG8/u mini is to insure the noise is not picked up between the filter and CB. This filter is not heavy enough to run a large RF amp. or linear, the "magnet-wire" would have to be #8 or 10 wire for any thing from 100 to 250 watt.

Good luck and any questions... ask
John

Jake:

Coax length makes no real difference, at the lengths you're talking about...
Have a longer cable made, and make sure to give yourself a couple extra feet,
just in case...

The only time coax length matters is for very long runs (over 100 feet), due to
line losses.

Dave:

Good info. Thanks for this, too...

Ok.. I think there's someone I could bother with this, helping out with the S readings....

A few things I've noticed using EZNEC to play with this (when I can get it to give me any output I can understand) are as follows:
1. This dipole seems to have an extremely broad useable transmit range (26.815 - 28.085 is all below 1.5:1)
2. The best SWR, according to the model, will be somewhere near 1.3:1
3. The highest efficiency seems to be at a point higher than the lowest SWR. (Could someone explain that?)
3. There's alot more to this than I even remotely understand... Is there a book or online resource that could explain what the heck an azimuth angle is, and what all the goofy greek-looking characters are? ::grin:: I guess I need to learn a bit more about the theory behind this in order to understand the model...

I guess you really can't just throw some copper in the air, tune for best SWR, and know you're "getting out".. I now see there's alot more to it than just that.

TIA, and 73

I want to thank everyone who helped me select an antenna for my CB radio.
Now a really out there question. What are the "standard" channels used on
the CB? In other words, is there a "community standard" channel such as 19,
29 for truckers? I know the VA State Police monitor CB9, but I never hear
any traffic on the channel.
Thanks

> any traffic on the channel.
> Thanks

Depends on your local area, really.... 19 is the "travel" channel. Truckers and others use it to share road conditions, etc....
9 is the emergency channel... the only time you should use it is if you are in an accident, you see something dangerous on the road (accident, injury, unsafe driving, etc), or you or someone you are with, find on the road, needs medical attention. It's important to keep this channel clear for emergency traffic, especially if REACT or the police monitor it.

There may be other channels the locals use. Generally, channels 35-40 get used by people running sideband. If you hear something on your radio that sounds like charlie brown's teacher on those channels, it's probably sidebanders talking. They keep to themselves up there, and it's kind of a gentleman's agreement that we respect each others' space. Makes the radio so much more pleasant to use.

Hope this helps fill in the holes.

Jake,
You can add more coax by using a 'double-female' connector, but add
cable in such a way so that the connector is weather protected (inside
the truck). It may not be as 'good' as one contenuous cable, but for
practical purposes, you can't tell any difference.
Just FYI, there are no 'magical' coax lengths, the 'correct' length
of coax is what ever will reach from the radio to the antenna. All
the
rest (except in special circumstances) is wasted.

Al,
It's best not to mount communications antennas near other antennas.
There can be/are interactions between antennas and one usually
'de-tunes'
the other. Mounting them that close will also be putting a ~lot~ of
RF
into your AM/FM radio (not good). It may not look as 'clean', but
things
will work much better if you mount the CB antenna at least 3-5 feet
away
from other antennas.

John,
Sounds like a very nice way of doing it! I would make one
change, instead of capacitors rated 15 -18 volts, I would at
least double or triple the voltage rating. May not be needed,
but doesn't hurt to be safe.
'Doc

1829. Re: Q: Mounting an antenna

I disagree, the cb will probably either blank out the am\fm or make noise over your speakers if you are using it when you transmit on your cb.
I don't believe that cb co-channel bleed over or strong am\fm stations have to do with mounting it close though.
I do agree that mounting it on the front fender will be more likely to cause ignition noise in the cb. Also, mounting an antenna on the side of the vehicle verses the center changes the radiation pattern from omni directional to more of a directional pattern that follows the path of the most metal. Antennas mounted in the proximity of your cb antenna will change the radiation pattern slightly. Mounting a shorter style antenna on the fender and close (2"-6") to the windshield pillar usually causes higher swr than when mounted on the roof top.
I would recommend you mount it on the opposite side of your vehicle to balance the looks and minimize the interference. I don't know what kind of range you want, but if looks is the top in priority and cb preformance is second, get a adapter box that plugs inbetween your am\fm radio and antenna that has a cb port on it. I think that they are still made. They used to use them with the (am\fm\cb\8 track players LOL). I have one and it gets a couple of miles range down the road talking to another short cellular look alike magmount style setup. I have even used it talking skip with a stock cb (no power).

Good luck

sideband,
I can answer one of your questions. An azmuth angle is the
direction (0* thru 359*) that the radiation pattern is 'pointed'.
Picture a compass 'rose' (dial markings of a compass).
The 'goofy greek looking characters', in most cases, are exactly
that... Greek characters. they usually represent various angles, or
values. I don't remember even a few of them so I ain't going there!

Hello SSB: I have replied below, or at least tried to:

sideband wrote:

> Dave:
>
> Good info. Thanks for this, too...
>
> Ok.. I think there's someone I could bother with this, helping out with the
> S readings....

No its not as simple as someone watching the S-meter! They need to have a 1 dB step Attenuator between the antenna and radio, and know not to transmit from the radio with the Attenuator in the coax line. I use a 2 meter handheld radio to blast back and forth with the S-meter readin guy, when tuning or doing antenna field strength measurement comparisons. I have measured the guys radio, as to what the differences are on the S-meter scale to start with, as a ballpark start figure.

The 1 dB step attenuator has a 0 to 12 dB, in 1 dB steps of range. The Attenuator is placed on the 6dB position. This allows the radio to see in 1dB steps either in attenuation or a gain in the receivers sensitivity, as the Attenuator is adjusted for more or less that the 6dB position. This also means that you start with the testing with 6dB attenuation in the coax line. And the other station uses only 1 watt of output power. You do not want to hit the S-meter readin guy with 40 over S9.

And then it takes a lot of practice. I have a separate Secret (unknown to Mr. S-meter readin guy) 6dB Attenuator that I throw in line, in the transmitting coax line to see if Mr. S-meter readin guy knows how to use the Attenuator, and is tellin the truth. No reason to bust ass if Mr. S-meter readin guy can't run his radio. Then after inserting the 6dB Attenuator in the transmit coax, I get a antenna field strength comparison reading of -5 to -7 dB, from Mr. S-meter readin guy at 1 mile away, I am good to go. Whats a dB or two among friends?

>
> A few things I've noticed using EZNEC to play with this (when I can get it
> to give me any output I can understand) are as follows:
> 1. This dipole seems to have an extremely broad useable transmit range
> (26.815 - 28.085 is all below 1.5:1)

Good deal you have taken the time to go and see how the antennas work according to what the EZNEC program says is ah happening, Bravo. It will take time and practice to get better.

Now to make you more dangerous, buy a MFJ model 259B antenna analyzer. I bought one for $200 dollars at HRO. Its way better than a CB type SWR meter, and a hole lot cheaper that renting a newwork analyzer.

When you design your antenna on Eznec, then run the SWR for the frequencies you want to cover, or interested in. Print the SWR curve on thick stock paper, and then measure the antennas SWR with the MFJ 259B antenna analyzer, plotting the measured antennas SWR onto the printed SWR curve from Eznec. If the SWR curves are dead nuts on, your a bitchen guy. If not,.... you need more practice. Be advised.... we all need practice!
And remember to document everything, the first time the antenna is measured.

This is how professional antenna, electromagnetic dudes design antennas. They start with a analytical design, have analytical gain and SWR curves already in hand (or on paper) before any antenna is assembled or any measurements are made.

Be advised:..... The guys who write the antenna modeling programs, and the guys who fill in the required data to satisfy the programs requirements screw up by the numbers big time. The guys who assembly the antennas screw up big time. The guys who run the range measuring the antenna screw up big time. So even after all the high priced talent has done their best, the product can be, big time crapp! Some old fart engineer who is really hard to deal with usually watches over the process, hopefully.

So do not become disenchanted if you fall on your ass 99 times in a row. Dust yourself off, collect your thoughts, and get a new game plan, and start over.

How good you are is, how close the (analytical) computer generated gain and SWR data, matches the measured antenna gain and SWR measurements. There are a few dudes who can design a antenna on the Eznec antenna modeling program, and be almost dead nuts on, when the analytical data is compared to the measured antenna data.

And you will find when the analytical antenna data doesn't match the measured antenna data, that you lied to Eznec, or did something wrong in the antenna assembly, installation, or just plain don't know. You will sharpen your antenna skills by leaps and bounds. You will see the antenna book writers, and seek the antenna hands on guys.

> 2. The best SWR, according to the model, will be somewhere near 1.3:1
> 3. The highest efficiency seems to be at a point higher than the lowest SWR.

Yep. But is the difference in the lowest SWR vs the highest gain worth any real effort in the antenna construction, tuning, or time? You half to know what the dB is, and how to figure it as compared to S-units, and $-units.

> (Could someone explain that?)
> 3. There's alot more to this than I even remotely understand... Is there a

> book or online resource that could explain what the heck an azimuth angle

> the model...

This is a great subject for discussion. I don't have the answer off the
top of my head. But I have a idea about it, but I am not sure of the
answer. Time to hit the books.

>
> I guess you really can't just throw some copper in the air, tune for best

>
> TIA, and 73
>
> -SSB

No you can't just throw up a wire, and become a big strap, and el-bow
all the guys off channel 6. And have all the Honey's callin ya up.

Again: Nothing that works in the electromagnetic field was a simple no
brainer design. Most everything was "Methodically" worked at, ran,
reran, redesigned, thrown out, modified, updated, and measured again.

Hello Doc: Yes half to agree with you there. We did calibrate the Kenwood S-meter as a ballpark reference. After the calibration, none of the knobs can be moved, and the radio just becomes a monitor. And use the S-meter and 1 dB Attenuator as the last comparison method.

I have heard the guys using a Digital Volt Meter, reading the voltage off the S-meter. I don't know if the DVM would load down the S-meter or not, may be worth a try? For a little more accurate reading?

Could always rent a HP Spectrum Analyzer I guess. But not until you can justify the cost. But you half to make do with what you have on hand, before using more expensive equipment.

Using a relative field strength meter in conjunction with an SWR meter
is a useful approach. Often, you can obtain the same low SWR reading
using very different settings of the inductors and capacitors in a
matching network, yet one of these will almost always yield by far the
highest field strength. It is instructive also that sometimes your tuner
acts like little more than a dummy load. On 40 and 15 I peg my FS meter,
with its sensitivity turned all the way down. On 80, with the sens.
control full CW, I can barely budge the needle no matter what I do. If I
relied only on the SWR meter, my feelings might be hurt that no one
answers my calls on 80 :)

Hey Scooter,
First off, don't go by the SWR meter on the radio. These meters
are simply there to check for problems, not to aid in tuning to
accuracy. You need to make sure you have 18' of RG8X coax. (or another
similar coax with 50 ohms of resistance)If your SWR's are higher on
let's say channel 40 than they are on channel 1, the antenna must be
shortened. Basically, you need to tune your antenna to the 11 meter if
you are going to use the CB band. Think of it this way. You want the
antenna to perform on 11 meter. If you decided to one day use the 10
meter band, you would shorten the antenna. If you wanted to use 12
meter, you would raise the antenna. The 11 meter wave is 11 meters in
diameter, so if you want to talk on 10 meter, you just shorten the
antenna by one meter. Now of course, you don't chop off a meter of the
antenna, especially since most antennas are 1/4 wave antennas. You
just keep cutting off 1/4 inch to 1 inch at a time until the SWR's set.
Let me know if I can help you anymore.

Hello & thanks for reading.
is there a high/low power on this unit?
If so, how do you switch it.
A friend just called and was wondering.
or there a site that has the manual I can download?
Thanks again...

Sideband, don't flatter yourself into thinking that you are the grand king of debate. My philosophy is that if you aren't intelligent enough to spell correctly, then what good is it to debate how much of an idiot you are. Gee.. The fact that you cannot spell nor can you use a spell checker (that of which most people have) is redundant, so I suppose it is unanimous that you truly are "just plain stupid."

Don't bother telling us how you know so much of homosexuals (and it's safe to assume that you -do- know).

Therefore; I have come to the conclusion that you WISH to remain an ass and you are not worth any more time.

you could do it a few ways a 150 to ground and a 1000pf in series to the relay or just put in 1- 135 pf cap 500v. just use silver mica and at least a dm19 . this is the actual value you need it is the same as a davemade 4 pill ,5, pill etc ..

A radio that is not moded for any swing, it puts out full carrier when unmodulated. Properly modulated means up to but not over 100% modulation on voice peaks.

>
>
> The largest carrier the radio will do which still yields a forward swing, I
> would think...
>

There would be no forward swing as monitored on the output with a watt meter or seen on the s-meter of a receiver. If you will look at the output of a transmitter using high-level modulation on a watt meter, you will see very little if any swing on the watt meter. Get swing out of your head, the signal doesn't have to swing to be good.

Electronic ignition? Whining noise? Ground loops? There could be a number of contributing factors for all this noise that you are getting. If you are hard mounting the CB to any type of chassis ground, you might have created a ground loop, whereas you would have to isolate that loop to get rid of some if not a lot of your noise. What kind of CB is this? I would suggest even running an additional ground from the chassis (where you connected the radio) to the negative terminal of the battery. This will provide both a near zero tolerance of grounding plus may get rid of the ground loop that may be present.

Be glad to. I've been smart enough to avoid them, since everything I've
seen written about them indicates that they're crap.

It's the type of noise that increases in speed and pitch when I accelerate.
Thanks.

Is it on a spring between the mount and the antenna shaft? If so, remove the spring, it ::should:: match up.

If not, you might do better to switch to a wilson 1000, and stay away from the "trucker" series on anything that has a large ground plane.

Hi all. Glad I found this NG.

OK, here's the situation. As funds were low at the time, I picked up a Realistic TRC-430 from a friend at work for $20 (Canadian). I have a 12' coax without coils or skein. Antenna mounted to the rear of my Jeep. Grounded. I have a military antenna. Off of a AN/PRC-77 set. 10' collapsible whip. Getting some nice feedback.

Have yet to get it "tuned". Rx others fine. Apparently I'm Tx'ing fine. 4 green bars (for those familiar with the 430) on virtually every channel. My question is, am I hurting the radio with this length of antenna? I was told I could be sending signal "back" to the radio.

I am illiterate with regards to tech specs, schematics, and the like. Am familiar with sky waves, ground waves, etc. Been briefed on 1/4 wave length ant. (Military training, expedient antenna for emergency use kind of stuff...I'm in the infantry, apparently I need to know this stuff :-0)

I figured the longer the antenna the better. I do quite a bit of off-roading. Against my better judgement and training, I go out solo. I figured with the longer ant., I would make for better range, especially when I'm out in non-cellular areas like mountains or in river valleys. Is my thinking erroneous?

Thanks for all of your patience with me. Looking forward to being as active here as I am in other NGs.

JP

First..Get off the fuse box and run straight off the battery..Run the ground to a seat bracket bolt (Since they are attached to the body you`ll get a better ground)

The internet is more than a global pornography network

Sounds like you need a little capacitance. Get a piece of bare copper wire about 14 to 10 guageabout 8 inches long. Fasten thes on top of the spring perpedicular to the antenna. Check the SWR. If it goes down you need a longer antenna. If it goes up slide the wire up the shaft to see if you can get a good match. If any position of the wire gives a good match or a better match you need a longer antenna. Why did you put a spring on it and trim it at the same time? Or did you try the spring and then trim it and try it again.

: be a 2:1 swr ... trim each end the same or add the same to each side to
: get your swr down to which every frequency is of your interest..

I have to disagree with this generalization. It is fine for any antenna that is close to 50 ohms impedance at resonance - but not a lot of help otherwise.

For example, some antennas are actually close to 30 ohms at resonance. You will radiate more power if the antenna is tuned for a SWR of close to 2:1, NOT 1:1. The problem is figuring out if that impedance is around 30 ohms or around 100 ohms - using just a SWR meter.

That is why it is recommended that the SWR meter is only used to make sure the impedance is within the range that the transmitter can handle. Tuning the antenna is done by field strength measurements - just tune for maximum radiated signal, and let the SWR become whatever it becomes. If it is out of the range that the transmitter can handle, then the antenna design needs modified in some way - then retune using the field strength meter.

: you can change the impedance by raising or lowering the ends of
: the dipole. if its for CB then the more vertical it is the
: better.

Correct. I have run 600 watts into 14 gauge wire, and it handled it
fine.

Slope the dipole down at the ends at 30-45 degrees, that will get the
impedance closer to 50 ohms - although it should be perfectly fine
even if hung level.

: The largest carrier the radio will do which still yields a forward swing, I
: would think...

No. You can get that with a carrier that is only modulated 10%. If the carrier is 4 watts peak - then you want a maximum of 16 watts peak when modulated.

Why is this? When a carrier is 100% modulated, the rf voltage doubles. Because the load resistance is fixed, this means that the current also doubles. As power is the product of the voltage times the current, you get 2 x 2 = 4 times the peak power.

The RMS voltage may, or may not change much on a meter. If it does change, it won't be by much for a properly symetrically modulated signal.

: shielding may help). Thanks.

Don't run the power lead to the fusebox - that is about the worst place you
can use. It connects the radio to the same point as all the noise generating
components in your automobile.

Run the positive lead, and the negative lead, to the battery - keeping them
as short as possible while avoiding other power leads and the vehicle computer
as much as possible. If the wiring can be run at right angles to the other
wiring, do so - don't bundle it with the other power wiring.

Fuse BOTH the positive and negative wires - at the battery.

: military antenna. Off of a AN/PRC-77 set. 10' collapsible whip. Getting some
: nice feedback.

That is not surprising. Many CB rigs have currents on the outside of the coax,
which is the principle cause of feedback or "RF bite". This can be cured
several different ways - all involving a choke that blocks such currents.

: Have yet to get it "tuned". Rx others fine. Apparently I'm Tx'ing fine. 4 green

: is, am I hurting the radio with this length of antenna? I was told I could be
: sending signal "back" to the radio.

The bars on the rig tell you little.

You might be putting the rig at risk - it depends on how it is designed. Some
fold the power back when the SWR is high, to protect the finals.

Power does not feed back into the rig - but the finals may not operate at
design efficiency - meaning that they would overheat.

: I figured the longer the antenna the better. I do quite a bit of off-roading.

In a general way, this is true for reception. A random length of wire will
generally not be the best performer for transmitting.

: Against my better judgement and training, I go out solo. I figured with the
: longer ant., I would make for better range, especially when I'm out in
: non-cellular areas like mountains or in river valleys. Is my thinking erroneous?

Yes. The antenna is probably a couple of feet too long to act as the
most efficient radiator.

Real quick JP..... Remove that antenna imediately and head to your local Radio Shack store. Pick up a 102" steel whip antenna ($15.) and screw that bad boy on to your Jeep. In order to safely operate your radio and optimize it's output, the antenna needs to be an exact length in proportion to it's operating frequency. The 102" whip is tuned for 11 meters (c.b.) and is arguably the best c.b. antenna on the market. If you don't have one in your area, get one through the mail from www.copper.com for just as cheap. Then start saving your pennies for a new radio! Just kidding. Terry

I also had a little trouble getting the jargon down, initially. Bill's right about the brevity, but 1) You have to know the language to understand everyone else on the highway. 2) You get more of the elusive "respect" you need on your radio from truck drivers when you speak the language. 3) It's a cool feeling to be one of the gang!

This is what I've learned, through a few weeks on the road with my radio:

The only ten codes you really need to know are 10-4 (OK, gotcha!) and 10-20 (Usually just abbreviated to '20' - this is your location, or the location of the person to whom you're speaking). The other ten codes are, I think, used by the CB wizards who took the time to learn them, but frankly, I wouldn't bother if you were just starting out. One thing about 20's I've realized - Make sure you know where YOU are, before you ask! Lots of times, location is given as the mile marker and direction on the highway of the speaker, and if you don't know where you are yourself, this info can get confusing. Exit numbers are also given frequently.

CB terms for police on the highway:

Bear, Smokey, County Mounty, and DMV. I include DMV, since you don't think of them as cops, but truckers definitely watch out for them, and they're good to keep in the back of your mind.

My formula for a proper way to see if anyone can hear you:

Say "Break 19 (or whatever channel you're on) for a radio check. Radio check on 1-9, please." I do this all the time, being as new as I am, and underconfident in my radio's capabilities. The break is used to interrupt the conversation that's going on between others on the channel. Be very careful not to talk over others. This is considered poor etiquette. The Break command can be used in any situation, suck as to ask a question about where the good eats are, or to inform about sighting a police car, etc... Use it primarily if there is activity on the channel, and don't over use it, since that can get annoying as well. When someone replies to your Radio Check, they'll say something like, "Go ahead Radio Check - you sound good!" or "Check's in the mail!" I sometimes ask their 20, so I can get an idea of range, but regardless, I'm always careful to thank them and wish them a safe drive. Use your own judgement...

Other random terms I can think of right now:

Got your ears on? - Almost everyone knows what this one means. Basically - Can you hear me?
Copy - As a question: "Did you get that?"
Copy That - " As an answer : "I got it."
Driver - Pretty much anyone driving on the road.

4-Wheeler - Pretty much anything that's not an 18-Wheeler
Come On - Also, "Come back" - This is used like you'd use "Over" on a walkie talkie - i.e. - "Anyone recommend a good burger joint around here, Come on?"
Alligator Radio - OK, so I only heard this once, but it was HILARIOUS. This dude asked for a Radio Check. Everyone replied - 'Sounds good Driver!" 20 seconds later, he asks for a Check again... This continued for 5 minutes. Finally, some Trucker with a good sense of humor said, "That guy's got an Alligator Radio - All mouth and no ears." Beauty...

Doing things, other than speaking information on the air:

This can include lots of sounds, but the ones I'll focus on are singing and whistling. Please don't do it if it's busy on the radio, or if you can't carry a tune. You'll only get voracious response, if you do. If you sing nicely, though, people can be VERY supportive! Good luck with this one. :)

I can't remember anything else right now. I'm sure I may have even screwed up some of them, myself. If you want to get all the ten codes, there are resources on the net, but I don't have a URL for you - just run a search for "Ten Code," and I'm sure they'll pop up.

I also have to add, that I am surprised that there's not more profanity on the air. I personally am not offended by it, but feel the others on the radio respect that there could be children listening (usually). In fact, when there is vulgar language going on, I usually hear another operator chastise the driver for opening his mouth in such a way. Depending on your perspective, this can lead to quite an interesting exchange, which only serves to make your trip go by faster. :)

Good luck with the radio. I'm a brand newbie, myself, and the gang here has helped me out a lot, so I feel privileged to help someone else, for once!
See you on the road. - Damien

1868. Power Mike - What level?

Newsgroup: rec.radio.cb
Date: 2000-08-15 04:26:28 UTC
From: "E. Damien Raba" <maskedmarvel@mindspring.com>
Message-ID: <8nagug$qn9$1@slb7.atl.mindspring.net>
Source record: 48211

Hey gang -
I just got an overpriced Cobra Power Mike for my radio (My car turned 100,000 and I needed to buy her a present! lol), but don't know what level I should shoot for. What's the mike doing, when I change the setting - just adjusting my volume level? Am I in danger of blasting someone away with it? Should I be tweaking it as I go, or should I set it and forget it? I've got it on 7 right now, and everyone said it sounded fine, but they always say that... Any help would be appreciated. Thanks - See you on the road!
-Damien
maskedmarvel@mindspring.com

BTW - I didn't get the echo mike, since someone here said they make you sound like you're 12 (to someone else's post). Can't remember who that was, but I was thinking of you in the Truck Stop today...

The best thing to do is either use a talk-back speaker, or adjust the mike while talking to someone else... just make sure they aren't your next door neighbor. They should receive you less than full scale - maybe around a 5 - 7... otherwise they may be too close to really tell you what level your audio should be at.. once you find your comfortable level, leave it.. don't keep pushing it up or down.. if someone is too close and you're over powering them with audio, they can turn down their RF gain.. :)

Wow - that reply was so fast, I didn't have time to unkey my mike! Thanks!

That's about the way I thought it should go. So long as I'm not pissing anyone off, or damaging my radio.
Your talkback speaker is a good idea - and sparked YET another question in my mind...
There's an output on the back of the radio for an external speaker. What I do sometimes is connect up the CD player adapter (to the tape deck) and play the radio over the stereo, if you know what I mean. I don't NORMALLY do this, since I can hear myself when I use the jack, and don't want to feedback. Any thoughts?

Thanks again for the lightning bounceback reply, man. VERY cool. See you on the road!

Needless to say wildbill, you failed to check and see what and who the courier was. It was USPS into Canada to John and if you had known this and used the USPS into Canada, you would also know that once it travels across the border different rules and laws superceed US laws. Also, we have not retained the insured refund as of this day and check on the status just about daily. Needless to say, we will send nothing anywhere unless it is with UPS anymore

BTW, you are shipping at least 10 packages a day, try shipping 50 to 65 packages daily and then figure the percentage of delays or problems that a courier may have at any giving time. UPS is still the most dependable and that is a fact. The packages that I just mentioned does not include the packages that are shipped from the wholesale end of our company to TA Truckstops, CB Shops, and many of the Internet dealers.

Jay:

Wow... that was a heck of a post. Lots of good information in there, too...

After I build the thing (I've decided to get 10 feet of Romex, strip off the outside casing, and use the insulated wires therein to build the dipole halves), and take down the data, I'll post it for you here in this NG, unless people don't give a rat's backsides how badly this CB'er messed up his antenna design, in which case I'll email it to you, if that's OK. ::grin::

Thanks again, everyone for all your help.

1875. Overdrive Communications CDL Products

Newsgroup: rec.radio.cb
Date: 2000-08-16 00:00:00 UTC
From: exportsrus@aol.com
Message-ID: <20000816041803.04810.00000950@ng-da1.aol.com>
Source record: 48391

I am proud to announce the beginning of Overdrive Communications CDL Product Inc. This Product Line has been in the steps of production for quite some time. These products were designed for the trucking market, for the drivers that put the groceries on the grocery store shelves. With this thought in mind, this product line can be used by the consumer as well. The new CDL product line will have the best products offered to the communications market in many years. We know that these products are of high quality and profitability due to the response form the 3 largest distributors in the country and two major Truck Stop Cooperation's wanting to purchase these products. CB Shops and Internet Dealers, we have even formed a program that will allow you to have these products with a minimum purchase. To inquire on the best and newest products to be released in many years, give us a call and we will give you the information on Overdrive Communication's CDL product lines.
~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
Thanks, Steve
Exports R Us
www.xportsrus.com
We also have the best wholesale prices for cb shops and dealers.

Uh, whoa... inductor? Grid? Huh?

I was hoping to be able to figure out, in advance, how long I'd have to make the two wire halves of a verticle dipole, cut those wires, attach them to a block of some sort, feed the coax, throw it up in the air, check the SWR's, tune it and go....

Now I need to build a gamma match or something similar to get this thing to work? I had always heard that the beauty of a Dipole was its simplicity...

So now I need to ask a bunch of questions, because (and yes, I'll come right out and say it) I'm ignorant where these things are concerned..

I'm a person of meager means. I can only work 4 hours a day (not by choice), so this dipole project, which will probably exhaust me when I put it up in the air, was conceived to both save me a few dollars, let me talk on the CB farther than the four miles I get out now, and get me some limited exercise.

1. How do I measure the resistance, inductance, and/or reactance at the feed point of a dipole? I have access to a relatively decent DVOM (if Fluke is decent), an SWR meter, and that's it...

2. Will I need a degree in Electrical Engineering to, once I've figured the above out, design and build this matching bridge/gate/whatever? I'm pretty handy with a soldering iron, and I do understand basic DC and AC electronics, (heck, I've even added my own little twist to the clarifier mod in the GrantXL/148/2000 that works VERY well), but I've never done anything such as this before, dealing with things I cannot directly measure. New ground for me.

3. Would it be simpler to design an antenna that had 50 ohms resistance in the first place, without the reactance/inductance, or would it be simpler just to make up the difference once an "efficient" design was created?

I know, I'm being bothersome, and for that, I do apologise. I'm just trying to understand and learn new things.

TIA, and 73's

Well, I saw someone asked the question and I had to respond. I ordered a "Turbo tuned export RCI 2950" and The thing sounds great. For the crap antenna I am running and a stock mic...it sounds unbelievable...It took about 5 days to get here not counting weekend. I am not sure about my watt-meter but I am thinking at full RF power it keys between 40 and 50 watts AM and I havent checked it on SSB but it is most likely 70+ watts. I have talked on it everyday so far and have had NO problems whatsoever if anything I am wishing I would have ordered one from their company earlier. So far everything is great, if that condition changes (which I dont think it will) I will be sure to let someone know =P But as I see their company now...I say go for it you'll probably be pleased.

That's what I was thinking, too.

Coffee, Try this... Take the radio out of the vehicle, put it in a ziplock bag (to keep out moisture), and put it in the freezer for an hour or two. Pull it back out, unseal the bag, put the radio back in, and power it up.. If it transmits and receives, it's almost definately the audio IC. If it doesn't, it still could be the audio IC, or something else.

Sometimes when the audio IC blows, it's temp sensitive. Getting it very cold sometimes makes it work (until it warms up again). Kindof a backwoods test, but it's helped me diagnose a couple of radios that have done this...

In any case, it shouldn't cost you more than $30 to get it fixed at a reputable tech...

On the Cobra 19, when the final pops, in my experience, the radio won't power up at all. If it were a driver or predriver, he would still have receive, just a VERY weak transmit. If it were the mixer, all he would lose would be transmit audio, or transmit carrier, or both of those, but receive would still be intact.

Just my two cents.

I have posted my current work with EZNEC (A very fine program, if you ask
me) on this dipole at http://phoenixrising.cac.net/antennas.html

I'd greatly appreciate it if someone could nab the file therein, check it
out, and see if I've missed anything and/or done anything wrong entering the

design into the program. ALL constructive comments will be greatly appreciated on this.

Thanks in advance, and 73's.

>does he mean Audio or Power or both?

Guess I left out some important information. The unit does power up. Channel selector works. Channel 9 switch works. I held the mic close to a handheld radio and when I keyed the mic it caused static in the handheld radio. I'm not sure what any of this means, but if you are let me know. I really didn't expect so many responses. This group is a fine bunch of people and I really appreciate your help.

Thanks,

Dave

The service was pretty good. I ordered my radio about 20 minutes
before they closed via phone on a tuesday and got it the following
wednesday and I live in NY.

I wasn't too sure about 'em either being so far at first but I'm from
tx about 40 miles from where they are so I had the option of chasing
them down when I go visit tx. As it turned out they have some of the
same techs I delt with before at a store they bought out in Marshall TX
and always had no problems with those guys either.. (good techs)

>told that Kraco's were built by Midland. So is this a good radio? It
>has two knobs that i've never seen on a CB - "RF Gain" and "Delta
>Tune". What are those for? And another knob switches from "ANL" to
>"NB". Is that like a local/distant switch?

B,

The chassis and PC boards used in the Kraco 23xx series were made by
a Japanese OEM supplier named Cybernet. The innards are the same as
those used in many radios sold by Midland, HyGain, Pearce-Simpson,
Lafayette, GM-Delco, Boman, and plenty of others from that same era.
They are all solid, dependable performers that will serve you well.
Yes, it's a good radio. It uses the famous PLL-02A synthesizer IC,
which can easily be made to cover a lot more than just the normal CB
channels, when worked on by a qualified technician who knows what
he/she is doing.

RF Gain: It isn't really a "gain" control, but a variable attenuator.
Use it to reduce the incoming signal strength (sometimes helps under
noisy conditions by improving signal-to-noise ratio). In normal use,
leave it set to maximum (fully clockwise).

Delta Tune: Varies the receive frequency about 1 KHz up or down to
help bring in off-frequency stations. This control is of virtually
no use in modern times due to the excellent frequency accuracy and
stability of synthesized CB rigs. Leave it set in the middle.

ANL: Automatic Noise Limiter. Helps reduce static. Helpful, use
it as required.

NB: Noise Blanker. In theory, supposed to help reduce engine noise
and other pulse-type interference. They don't work well, but they
are better than nothing. Use it as required.

RG-6 is thicker then RG-58. RG-8X is closer in size to RG-6 and has less
loss then RG-58. The use of solid conductors in a mobile environment is
not a good idea. Stick with stranded wire, although this precludes the
use of F connectors.

>get it ?
>

It is my understanding that a channel guard is a device that once installed, beefs up your receiver so that it wont be so succeptible to adjacent channel "Bleedover" which in turn allows your receiver to pick-up low-level distant stations easier, since there is less cross channel interference. I really dont know much about these devices, since I primarily run radios that have at least
> 80db of adjacent channel rejection.....ie; Trams, Brownings. I think some of the fellows on this newsgroup are pretty well versed in the uses and applications of the "Channel Guard", maybe soon, you'll get a more detailed, knowledgeable answer soon. good luck to you.....

What are you complaining about you are one of few that has a cobra 25 with FM.

Sounds to me like the radio is heating up when you modulate. Just a thought.

Clipping of the AM signal also can sound like and off frequency signal. Did you do any real test of just play by ear?

1904. Re: Home-brew helical wire length

Newsgroup: rec.radio.cb
Date: 2000-08-16 00:00:00 UTC
From: Cory Papenfuss <papenfus@juneau.ece.uiuc.edu>
Message-ID: <Rqxm5.990$9N1.16835@vixen.cso.uiuc.edu>
Source record: 48420

Hey... I guess I finally got it figured out, and everything about needing more wire was right. The tough part was that it didn't seem to really make much difference how long the wire was (so long as it was long enough), but the distribution of the coil was very important. I farted around stretching, squishing, redistributing, etc the winding of about 275" of wire on it, and eventually got a pretty good match. (I don't have a VSWR meter, but I build one of the LED bridge indicators and measured the "current" with a voltmeter). I've sorta calibrated this "meter" with known loads so I know I'm better than 2:1 VSWR.
I guess if there's a conclusion to all this, it's that wire length is not the way to trim up a helical antenna like this, but coil distribution is very important. In the end, the first half is about 1" separation, and the top half is about 1/4" separation between the windings.
BTW, the network analyzer has a pretty weird impedance spectrum on this thing. It happens to be about 40+j3 at 27 MHz, but below that, it stays a good match (dips around a bit, but better than 3:1 or so) down to 24 MHz. I suspect that the funky wire distribution and relatively heavy guage (14 or so) help broaden the resonance bandwidth.

-Cory

: As I said before. It takes much more than 104 inches of wire on a
: physically shortened antenna. For example, a KW7 Firestik has
: 265 inches of wire. A upper center loaded 6 foot Hustler has
: about 138 inches of conductor. You need considerably more
: than 104 inches of wire on a fiberglass form.

I'll tell you what to do: Take that darn radio shack antenna and give it to someone you hate.

When you need wire and connectors, go to radio shack. Otherwise, let people interested in Tandy computers go in there. =)

You won't blow anyone away with a power mic, but you may run the risk of a squeal if you turn it up too high. Depends on the mic. Just keep it set mid-range and you'll do fine.

Find someone with an SWR meter (or go buy one) and check them out. You want your ratio as close to 1:1 as possible. If they are too high, that is what you were told about "sending signal back to radio" If the antenna/coax setup will not allow all of your signal to get out, it will feed back through your final transistor and eventually burn it up.

Usually to correct SWR you have to either change the length of coax or "trim" the antenna. How much depends on how far you're off. I'd find a shop and let them make that determination.

Also, the length of your antenna doesn't the slightest thing to do with range as far as a mobile radio is concearned. Just make sure your radio is throwing all it'll throw and your ratio is as flat as it'll get and you'll be heard.

You won't get interference from your regular AM/FM antenna, but you will get some weird looks with it on the front of the vehicle. Put it on your rear bumper. You'll get a better ground and it'll look better.

Don't add any coax to your rig, the length is 18' foot for a reason. You'll mess up your SWR reading and you'll burn your radio up. You need to find a way to make what you have work. My question is this, what kind of hellacious truck do you drive that 18' of coax won't reach? I think I'd like to see that monster! =)

Jake <jakepkoe@yahoo.com> wrote in message news:8C56E295BE7F4585.A54DECB8F070B570.A74728272B949D9A@lp.airnews.net...

Truckers use 19 the most, channel 9 is used in a lot of towns for emergency use, that is why you will not hear a lot of traffic. People stay away from that channel as a courtesy in case someone needs a clear channel to call for help. Some state troopers monitor it, and some towns have unofficial public response teams that monitor CH9 on a volunteer basis in case someone needs help.

Basically use whatever channel you want, you have 40 to choose from. A group from my town always used to talk on 3. Just depends on the people.

> windings.

A KW-7 has the coils spaced apart at the bottom and they get closer together at the top. The last 3 or 4 inches is a tightly wrapped coil at the top. Current does not pass well through a coil, and the voltage peaks at the end of an antenna. Since power is equal to voltage times the current, any base loaded antenna starts with a disadvantage. I have a KW-7 mounted to the bumper of a Jeep. 4 feet stick over the top. It works almost as well as a KW-7 on the trunk of my heavy Chevy. With a preamp, I can hear 95% of what the base stations do. With a two pill on SSB, I can talk farther then I hear. (I hate when that happens!)

If its a later Ford its definitely the pump.
To test turn the car off. Now with the radio on turn the ignition to the first position don't start it. This will energize the pump and you will momentarily hear a whine come through the radio.

Is the stud bottoming in the mount? I assume it is the same coax. You may need a longer whip due to the surface area of the van but the 3:1 seems like you are shorting out or not making a good connection.

As luck would have it, I am in possession of a PRD angle of reflection coefficient bridge. That's all it does, give the angle of the reflection coefficient. But as you point out, this is necessary information for creating a match.

It's a neat looking gadget, and serves very well to estimate a job applicant's ability to think beyond the box when given an RF problem.

Cheers,

Cortland

>range as far as a mobile radio is concearned.

Yeah that makes a lot of sense. That is why those 2 foot antennas perform so well. People must just like the looks and incovenience of a 1/4 wave.

Please stop passing false information out. If you don't know what the hell you are talking about, don't post.

1923. Re: Few Q's from a newbie...sorry (Long?)

Another dumb quote: ">Also, the length of your antenna doesn't the slightest thing to do with range as far as a mobile radio is concearned. Just make sure your radio is
>throwing all it'll throw and your ratio is as flat as it'll get and you'll....."
Don't listen to this stupid advice. The length of your mobile CB antenna actually has the MOST to do with your range. Put "brand names" second, & buy the longest antenna you are willing to mount in your mounting "spot" for best results. If you are using say, a 3 foot stick on your roof, changing to a 6 or 7 footer in the same mount would give you better range, much better than trading your "firestik" 3 footer for a K40 or Wilson 3 footer. There is no way, for example, you can unscrew a 6 or 7 foot skipshooter, & put an (any brand) 2 or three footer in the same mount & get better or even the same overall performance. The only way I see a "shorter" antenna working the same or better would be if you put a 3 or 4 footer on the roof, VS the larger antenna down on the bumper, because the "shorter stick" would actually be "higher up" ("longer measurement from the ground to the tip"--again "length related) & unobstructed by the vehicle's body.....

This should not be a problem to add the cable lenght you need. Although they used to sell REALLY crummy cable, for the past several years Radio Shack been selling is not too bad and you can buy a pre-made 10' patch cable. There are two couplers you can buy. I don't know the model of the most popluar, but it is a double SO-239 female for jumpering two cables together. Another is a PL-258, very similar to the first but it is continously treaded. Both will work fine. A single piece of cable is better and stranded center conductor is better in a mobile enviroment, but patching the cable at CB frequencies will cause mininumal loss. I would cover and connection with coax seal. Stickly stuff similar to the compound they use to plug the end of conduit where service entrance enter buildings. Most better radio centers will carry it, Ham, CB. I though I have seen it at Radio Shack a while ago but you will have to check. I got mine from a Ham Radio Store in Milwaukee, Wi.

I went with a continuity tester, and there are no shorts. The 5 foot Firestick on top of my van works better (as far as SWR) than the Wilson 5000. Go figure. The firestick is a good antenna right? I'd probably get my signal out further with a tuned wilson though right? Thanks

<< Is the stud bottoming in the mount? I assume it is the same coax. You may need a longer whip due to the surface area of the van but the 3:1 seems like you are shorting out or not making a good connection. >>

surre there is and since i am a GM guy my self i will help you .

1 : wire the radio to the battery , not the fuse box
2: if you have old spark plug wires get new one
(high shield ones , i got some from accel)
3 : get a power line niose filter , rflimited has some
ask your local cb shop about them .
4: check the ground on the engineusually runs from
the block to the battery or right to the frame

those are the 4 main things you can do for engine noise , they should help a
bit , other posts in this group deal with fuel pump noise , check them out to

<preemptive flame snip>

Coax length (under 100 feet) does not matter. Period. End of Story.

I have 17' 2" of coax going from my radio in my car to the dipole I have mounted on the trunk. When I was still driving truck, I had 2 1/2 feet from my radio to the receive amp, 8 inches from the receive amp to the linear, and 11'2" out to the antenna... Had a nearly flat match, and close to a 1Mhz bandwidth (1.5:1 or better). Another driver didn't believe that coax length didn't matter, so I told him to go buy 2 3 foot jumpers and an 18 foot section for the antenna... He did, figuring the C note we'd bet on it would cover the costs.... I showed him the SWR's on the radio, wrote them down in a notebook, then went to town with the 3' and 18' sections... When it was all done, I checked the SWR's again... guess what? NO CHANGE.

I don't know who brainwashed people into thinking a feedline has anything to do with SWR, but they were WRONG. The only length that matters is the length of the antenna.

Can you put the antenna (Wilson) on someone else's vehicle to test it. Or try a longer whip. Wilson has them. Firestick is okay a little flimsy compared to a SkipShooter. I don't know if the 5000 would get you out farther probably more broadbanded though.

From: "David P." <L65diesel@ev1.net>
Message-ID: <splsu2mtr5j179@corp.supernews.com>
Source record: 48450

I have been told that there were some differences in the Turner 2 desk mic, but here is how mine is currently wired.

Lets see if I can make at least a little sense out of this. There is a left and a right side, with 3 pins on each side. There is also the relay switch with pins 1,2,3 going down. Lets start on the left.

On the very top there is a ground spade screwed into the switch.It has the mic wire shield on it that also connects to pin 1 of the relay switch. There is also a black jumper here that goes over to the bottom right pin

The top left pin has the red mic cord wire plus a red jumper going to the bottom relay switch.

The middle left pin has a black jumper going to pin 2 of the relay switch.

The bottom left pin has the black cord wire going to it.

Now to the right side. The top pin has the black battery wire on it.

The middle right pin has the white cord wire plus a yellow wire that goes to the volume knob, connected to the "-" side of the silver looking capictor.

The bottom right side has the black jumper to ground and another black wire that connects to the ground tab on the volume switch.

Try this, and if it doesn't work we will try again and see where things are different. This turner I'm looking at doesn't sound as good as my other one so there may be a wire connected to the wrong point. Someone else reading this on the group may have some advice as well.

If you need any more directions give me a holler.

So spit 'em out... let's hear 'em. I've proven, in the real world, multiple times that coax length simply does not matter in relation to SWR. So I'm curious as to what in the "whole picture" would be a good reason to tune a shielded, non transmitting portion of an antenna system...

1939. Re: Homebrew dipole (somewhat of a long post)

Newsgroup: rec.radio.cb
Date: 2000-08-16 00:00:00 UTC
From: ehsjr@bellatlantic.net
Message-ID: <399B0423.8338BBEC@bellatlantic.net>
Source record: 48455
Cross-posted to: rec.radio.cb,rec.radio.amateur.antenna

No, you are not being bothersome. But you
got a lot of answers including some bad
information which could lead you astray.

If all you want is to put up a simple antenna
that works, and are not into designing the
the very best antenna you can, then build
a dipole. Determine the length of the elements
(2 pieces of wire) by the formula :
495/frequency where frequency is the frequency
you want the antenna to work best on and is
expressed in mhz (megahertz), and the result
of the computation is feet. For example, at
28 mhz, the result would be about 16.6 feet.
Divide that by two to get the element lengths.
You would need two elements 8.3 feet long. That
will give you a good starting point somewhere
near 50 ohms impedance at 28 mhz. You can then use
an swr meter and adjust the element lengths
for the best match as indicated by the meter.
You must shorten (or lengthen) an equal amount from each
leg of the dipole. You make your swr measurement
with the antenna installed, then lower it, shorten say
1/2 inch from each end. You raise the antenna back
to its proper height and measure the swr again. You
repeat the process of lowereing, shortening, raising and
measuring until you are satisfied that you've got a low
enough swr. If you find that shortening the elements
raises the swr, then lengthen them instead.

The exact impedance of your dipole will depend
on surrounding conditions, how close it is to
the ground and so forth, so the use of the formula
is only to get you in the ballpark.

Now, the rest of my answer will be in response
to your post, and will be somewhat harsh.

sideband wrote:

> Uh, whoa... inductor? Grid? Huh?

> some sort, feed the coax, throw it up in the air, check the SWR's, tune it and

> go....
>

You already know that stuff. You posted it in your first post.
Your first post indicates you are looking for an optimum
design, not the soft bullshit you posted above. If you
want to optimize you gotta learn. You also indicated
you are envisioning running a 200 watt amplifier. "Serious
overbuilding" you called it.

> Now I need to build a gamma match or something similar to get this thing to work?
> I had always heard that the beauty of a Dipole was its simplicity...

If you want advice, then spend some time reading it properly.

> So now I need to ask a bunch of questions, because (and yes, I'll come right out
> and say it) I'm ignorant where these things are concerned..

No problem when you don't know, and no problem when
you ask

> I'm a person of meager means. I can only work 4 hours a day (not by choice), so
> this dipole project, which will probably exhaust me when I put it up in the air,

> the four miles I get out now, and get me some limited exercise.

Build the 1/2 wave dipole you mentioned in your first post, and that I
outlined above and that has been explained in other posts. Undertsand
that we cannot optomize it for you to exact dimensions, which will
depend in part on the environment where it is installed.

> 1. How do I measure the resistance, inductance, and/or reactance at the feed
> point of a dipole? I have access to a relatively decent DVOM (if Fluke is
> decent), an SWR meter, and that's it...

You don't. But my post was prompted in response to a post
that told you that you measured impedance with an swr meter.
I corrected that so that you would not be mislead.

>
> 2. Will I need a degree in Electrical Engineering to, once I've figured the above
> out, design and build this matching bridge/gate/whatever? I'm pretty handy with a
> soldering iron, and I do understand basic DC and AC electronics, (heck, I've even

> VERY well), but I've never done anything such as this before, dealing with things
> I cannot directly measure. New ground for me.

If you build a 1/2 wave dipole as described and feed it with 50
ohm coax, you will not need a matching network. You will
adjust the length of the elements for the best match.

>
> 3. Would it be simpler to design an antenna that had 50 ohms resistance in the
> first place, without the reactance/inductance, or would it be simpler just to

> make up the difference once an "efficient" design was created?

Yes/no/maybe - depends on what it is you have in mind. If all you
want is simple, go with the dipole. If you want distance and all
other factors are secondary, go with a beam, or a quad, or whatever -
but you have to be able to choose between the tradeoffs. That's
what engineering is all about - creating the best design for a given
set of circumstances.

> I know, I'm being bothersome, and for that, I do apologise. I'm just trying to
> understand and learn new things.

Again, it's not bothersome. But expect to do some work in
reading and trying to understand the answers. And understand
that you set a real bad tone from the outset with your mention
of the 200 watts for a CB antenna. Hams love to help others,
as a general rule, but not to help in illegal activity. 200 watts
on CB is illegal, and, frankly, pisses a lot of us off. You
already received some replies where that is evident.

200 watts is legal on the ham bands, and we regularly
talk all over the world. There is no legal restriction
on you becoming a ham in the USA (I'm assuming
that's where you live). Yes - you have to work for
the license. That's one of those "engineering" choices:
am I content with CB and its limited range, power
limit and bandwidth, or am I willing to work for
the latitude that ham radio would allow?

Nothing wrong with being content with CB.
But your expectation of posting a question
here, which happens to reference the
inclusion of possible illegal activity, and receiving
a single, well informed and crystal clear set
of instructions to enable you to do what you
want is unrealistic. Those of us who have answered
have, for the most part, tried to be helpful. In
return, do us, and yourself, the courtesy of reading
what was said carefully.

Wayne,
Learn to read. This is a 2970 (100 watt model) not a 2950. While you may be able
to get a 2950 for $250, I don't think you will find a 2970 new for $250.

Thanks for wasting bandwidth with your non-constructive comment

1941. A question about fuel pump noise

Newsgroup: rec.radio.cb
Date: 2000-08-16 00:00:00 UTC
From: Ed McDaniel <spooble@bcn.net>
Message-ID: <spm1242dr5j83@corp.supernews.com>
Source record: 48457

Thanks for taking a moment to help.

I have narrowed down the noise in my radio to the fuel pump. It goes away with the antenna unhooked. Will bypassing the fuel pump with a capacitor help with noise that comes in via the antenna? The antenna is a body mount on the right rear of the cab of my truck with a good body ground.

I went to the local Radio Shack to purchase the capacitor (.01 mf @ 35 to 50 VDC) and found the proper mf but found the rating values to WVDC not VDC. What is the capability of a 200WVDC for instance. What value should I be looking for.

I have learned a lot from this group already. Thanks in advance for all your help.

Automatic Man

The quality of coax does matter with increase in frequency.

For instance RG58 gives more than a 3dB loss for every 10 metres in length
at 430 MHz.

I used 7 metres (23ft) of Mini 8 in my Land Rover Discovery and I used the
shortest possible route from near my left knee (driver's seat) to the
centre-top of the rear door, so 18ft isn't as big a figure as you'd think.

Not everyone wants to use a mag mount in the centre of the roof (especially with twin sunroofs).

Mounting on top of the rear door gives an example of the use of the roof as a ground plane, I lose five S-points when the door is opened.

I'm certain that mounting on the rear bumper is more lossy than mounting on the cab roof, due to transmission line losses and losses in your TRX due to the size of your ground plane.

Have fun.

Ed,
That capacitor's voltage rating should work fine. In fact, any capacitor value of 0.01 to about 470mF, at twice the voltage applied to it should work. As long as the voltage rating is two or three times as much as that applied, it really doesn't make a lot of difference.

What good is a power filter with out a
shielded cord grounded at both ends?
Unshielded cords between the filter and
radio can put back RF noise that the
filter just filtered out!
Cheers,
John

The way that I read is that it is a crystal filter that narrows the
bandwidth of the receiver in the IF section. It also has an amplifier stage
that brings the attenuated narrower signal back up to where it was before
filtering. This is a common add on that is found in the more expensive
amateur radio gear. I would recomend it for any radio where bleed over is a
problem. If it works, the price isn't bad.

Wonder if it is sold in kit form?

From: G SEVEN <superiorwavelength@prodigy.net>
Message-ID: <8nfktc$1d90$1@newssvr05-en0.news.prodigy.com>
Source record: 48470

I am in the process of building a 400 amp power supply and am in need of some info or a formula on how much filtering its going to need.
I was thinking of going with those big 1 Farad caps (per 1k watts), I just need to know how many to use. This is going to to be a variable supply, 220V in and 15 -21 VDC out. I have a 2 x 200 amp transfomers that I am going to use for the job. Any ideas anyone?

Um, no.

18' is a half wave. 12' is 3/8. Velocity factor weighs nil in a feedline. It only really makes a difference in the radiator (antenna), and that difference can be negated by many other factors.

I am familiar with this type of whip, except the ones I used (probably the old style) were made out of aluminum instead of fiberglass and had a heavy cord inside them and the base section was spring loaded to keep the cord tight. If you could eliminate the top section and be around 102 inches long it will preform better. Even if it measured 100 inches and you had a 2 inch tail of the braided cable sticking out of the top to make up that 102 inches.

I would just buy a 102 " whip, it sounds like it would be more rugged.

antenna.

You mean like they used on the old 46's and 49's? They had a base load that you could dial in the frequency range. Some even had a cable that hooked up to the radio and would automatically change the load in the antenna whey you changed frequcncy. Don't know if they went below 30 mhz though.

Well, I also stated in my post that I wasn't a HAM, yet... I am studying to get my ticket, and I was hoping to build this antenna so that, with minor modifications, it would work on 10 meters when I was done with it. In this way, I hope to avoid a major rebuild of the antenna when the ticket does come... I'm not running power on the base station now... I think my neighbors would get annoyed with the bleedover into their TV sets in the apartment building.

I'm trying to build the best dipole antenna I can, that will radiate as efficiently as it can, and do it once. After the accident, I don't move around as well as I used to, so I had wanted to be able to build something that would last me a very long time, be stable, and would be able to be improved when my needs change (read: when I get my HAM licence).

I hope this confusion hasn't put many people off. I didn't intend for that to happen. I was planning on overbuilding so the antenna would be able to change with my needs without massive re-working.

Wonder if you could change a component in your fs meter to work better on 80
meters also? Circuit is probably acting like a hi pass network......

How about remote mounting the antenna for the field strength meter outside
and monitoring it from the shack?

What about this one.Have you seen any of these new cobra 25 radios modulate the radio off frequency?At a carrier with no modulation the radio is on freq.,but when the radio is modulated,it shifts down on freq.This is verified with a clearifier on am to another radio.The frequency does not stay stable while modulated.The voltages are stable and the output of the oscilator is stable.Did cobra change the pll chip?Let me know what you think and I will tell you if I checked it.Thank you in advance.PEACE.

How can a pep meter tell you if you are getting 100% or more modulation?If a radio is set up to swing from 4-18 watts,there is no way you can tell with a meter that it has 100% modulation.The swing thing is only allowing the transistor to run out of saturation is it not.The modulation has not changed.If a radio is set up to key out 18 watts without modulation,what happens?Is it called thermal runaway from heating up because you add modulation at that point and it can not handle it.Well maybe not thermal runaway but you know what I am saying.Heat on a solid state device is its worst enemy.I do not remember everything that I was told in school but I do remember being told to prevent as much heat as possible.Heat is a waste of power.PEACE.

doesnt this same phenomenon(distortion and clipping) occur with
overmodulation, and such as swinging form 2 watts to 30 watts?
Is there a happy medium? I guess it depends on the application. because at
keydowns if you dont have like 150%+ modulation and in my opinion swing
forward you just dont get the trophy...

Hi all,

I'm new to the CB world and was wondering if some of you knowlegable people could help me out. I recently bought a used radio (Cobra 19 Plus) and all of a sudden it won't transmit nor will it receive. I hooked another radio to the antenna and it worked fine so I guess the problem is in the radio itself. Would there be a straightforward and simple cure for this? I know it's a cheap radio, but if there is a simple remedy maybe it's worth an effort.

Thanks,

Dave

1968. Need Info on Old Kraco KCB-2330B

Hi,

I just inherited a Kraco KCB-2330B. It's beautiful, and looks as close to new as you can get. The date on the back is June, 1976. I don't have any manuals or anything, and I can't find any information on-line on this radio. Does anyone else have one or know anything about it? I was told that Kraco's were built by Midland. So is this a good radio? It has two knobs that i've never seen on a CB - "RF Gain" and "Delta Tune". What are those for? And another knob switches from "ANL" to "NB". Is that like a local/distant switch?

Thanks!

S-meters give a relative reading, none are really calibrated accurately, and even if you calibrate it on one band it won't be in accurate when changing to another band. For accurate s-meters, you have to go to lab quality receivers costing much more than a Kenwood ham rig.

Actually, civilian hardware minus the whip. If anyone is familiar with this type of whip, it is in 7 sections, brass fittings that slide into each other, [[much in the same manner as a typical "dome tent" spar one would use for camping]]. Instead of the shock-cord inside, it's like a steel cable. At the top there is a threaded end with a vertical cut, a nut on that and the cable going through the center of all that. pull the cable, all the sections connect themselves. The nut is tightened down to "trap" the "cable" with about 7" hanging out the very top.

Would I be way off-base to assume I could, maybe, knock out a section of the fiberglass pole that houses the "cable" to 102"? A guy at work mentioned this might be possible. I have my doubts.

The mount to the antenna is a steel 90 degree angle bolted right to the body of the Jeep. So, as mentioned, the only military kit would be the obsolete antenna. (New system being phased into the system all HF stuff/ built-in crypto etc.). Oh and the cabinet I have it in is a 50 caliber ammo box, bolted to the floor like a center console. Wires running to the battery direct feed style. (With reference to the engine noise thread--- I have the same problem... I digress).

Sorry to ramble, I tend to get long winded. I have this thing for detailed explanations, even if my questions tend to be somewhat vague...*shrug* apologies.

> get it ?

I saw it for the RCI 2950/2970 radios at express electronics here's
what they say it does taken directly off the web site.

Channel Guard - This is the installation of the CB City International
channel guard. It is a dual-crystal inline IF amplifier and filter. It
allows for a zero-gain filtering of incoming RF signals. It greatly
reduces static ground noise, and improves adjacent channel rejection
significantly. We tune every radio before and after the installation
for minimum noise, with no loss of signal. This allows for more signal
reception, as we can eliminate the background noise.

>
> but i have the delta force and it has crappy channel rejection . this
sounds
> like it could be for me

as I said in the other post I didn't really notice much difference with
rejection but then again all the other 2950's I've had were pretty good
with dealing with it anyway.

for more info talk with the tech guys at exportradios.com it's listed
for $65 to install in a 2970 but I don't know if that's their set
price. the radio I bought was a package type deal with that as part of
the radio setup.

ummm. 9 feet is closer to a quarter wave at 11 meters (actually a
little long) 17 is half wavelength.

if he can set the length of the telescoping antenna then he could set
it at aroun 102-104 inches and not need a tuner at all. just an swr
meter long enough to get it tuned for the right length and be good to
go.

If it neither transmits nor receives, start at the main fuse and work from there. Perhaps you have no power at all because the fuse blew. If so, find out why the fuse failed.

:
: Dave, KG5XR

This is fine for a known antenna design hung in a proper location. By design, the impedance will then be within a reasonable range at resonance.

If working with an unknown design, or installing the antenna in an unusual location - then all bets are off. That is where the field strength measurements become necessary.

Examples would be a dipole placed in the attic or under the eaves of a house. Such close proximity to conductive objects will move the resonant impedance away from the designed range.

Not that this is necessarily bad - it might even be advantageous.

Trying to verify frequency by listing on another AM radio is a waste of time.
Try listening on a SSB radio. Tune the radio so the carrier produces a
comfortable tone (don't zero beat - the test is not as precise that way).
Now, have the person speak, if the carrier produced tone shifts, then there
is a problem in the Cobra.

: 'too close'. I was thinking 2-3" away, and using the factory bezels and
: such to make it look like an OE installation. I don't want to drill the
: hole, do the install and then find out I have a ton of interference. Any
: input regarding distance from other antennas would be appreciated.

I would not recommend that procedure, for several reasons. 1) the
antennas will interact - so the tuning of your CB antenna may be quite a
bit off. 2) You would be pushing more RF than necessary into the AM/FM
radio - which could cause problems, even if it is only noise on the radio.
3) All radios radiate - your AM/FM radio could interfere with the CB radio.

If you want things to look "clean", just mount it on the other fender, using
the factory bezels etc if possible.

: So your saying that tuning an antenna with a swr meter is wrong ..max field
: strength does not guarantee lowest swr .. how can you go wrong by tuningan
: antenna for lowest swr

Here are a couple of examples.

A dummy load has an SWR of 1:1, but it makes a lousy antenna.

Many antennas, without matching networks, are not 50 ohms - matter of fact, most are not. Now, an antenna radiates the most power when resonant. Let us assume that the antenna is 25 ohms when resonant. That means, to radiate the most power, you need to tune for a 2:1 SWR - not 1:1. But how can you tell this from tuning the antenna to a 100 ohm impedance - which would also produce that 2:1 SWR? That would be even further from resonace.

In short, SWR meters and field strength meters work well together, but the SWR meter is necessary only to make sure that your transmitter can couple safely into the load. Field strength is all that matters - you don't transmit SWR.

The question was how do you measure impedance.
An swr meter does not measure impedance. An swr
meter (more properly, VSWR meter) measures a
ratio of the voltage in the forward direction (ie out
to the antenna) versus the voltage in the backward
direction (ie back into the transmitter, reflected from
the antenna). The bigger the reflected voltage, the
higher the swr. An swr meter, nevertheless, is a good
indicator of whether impedance is matched at 50 ohms,
as you pointed out. It is certainly not the best.

But impedance consists of 3 elements - capacitive
reactance, inductive reactance and resistance.
A true impedance measurement would be expressed
as so many ohms, not as a ratio. And, typically,
one would find expressions that look something like
this: 23 +14 Jx That reading indicates the the
complex impedance consists of 23 ohms resistance
plus 14 ohms inductive reactance. If the expression
were 23 -14 Jx it would mean 23 ohms resistance
plus 14 ohms capacitive reactance.

Now, why is this important? Because you want all
of the power going out to the antenna to "see"
nothing but resistance. In the case of an antenna
with 23 ohms resistance plus 14 ohms inductive
reactance (23 + 14Jx), the only power radiated
by the antenna is the power across the 23 ohms
resistance. The power across the 14 ohms inductive
reactance is wasted. So - you want to get rid of
that +14 Jx, even if it leaves you with 23 ohms,
and an swr worse than 2:1. Why? Simple.
You transform the 23 ohms to 50 ohms. Now there
is no reflected voltage (no reflected power when there
is no reflected voltage) and all of the power reaching
the antenna is radiated, rather than having some of
it wasted in Jx. There are a number of ways to
transform the impedance, at the antenna, to achieve
the maximum radiation of the available power. Pruning
the antenna (cutting the wires smaller and smaller while
observing the swr reading getting closer and closer to 1.1
to 1) is one example. In a beam antenna (which would
have an impedance in the low to mid 20's with some
Jx reactance as in teh example expressions I used) a

typical transformation AND elimination of the Jx is
accomplished with a gamma match. A gamma match
includes a transmission line transformer (which introduces
+ Jx (inductance) AND transforms the resistance from
23 ohms to 50 ohms) and a capacitor. The capacitor
introduces -Jx. The +Jx is unavoidable, as it is necessary
to attach the feed line to the center of the element and to
some point away from the center to achieve 50 ohms
resistance. The length of wire that allows attaching the
center conductor of the feed line (the shield is attached
at the center) to the 50 ohm point somewhere out on
the element away from the center introduces the extra
inductance - the +Jx. Now, if you have an accurate
impedance measurement and know how much inductive
reactance has been added to get to 50 ohms resistance,
you can compute the value of capacitance needed to
produce an equal amount of - Jx. Finally, in all cases
above where the term resistance was used, the correct
term is radiation resistance. I won't get into a discussion
of that here, other than to say that it indicates that the
signal it (the radiation resistance) "sees" is the signal
it radiates out of the antenna. It is not the same as
the resistance we talk about at the electronic component
level, The signals those resistances "see" are converted
to heat, not radiated.

That is important stuff if you want to really make your
antennas perform well. The simplest concept is this:
you can get a good match (ie swr is 1.1 to 1) and have
a lousy radiator. If you had, for example, 1 ohm of
radiation resistance plus 49 ohms of inductive reactance, then
most of your signal would be converted to heat in the
inductor - only about 2 percent would be radiated.
Clearly, you would want it to be the other way around!
So, that's why there needs to be a distinction made
that swr meters do not measure impedance.

John M. Boulware, Jr. <wqdrjohn@mindspring.com> wrote:
: Find someone with an SWR meter (or go buy one) and check them out. You want
: your ratio as close to 1:1 as possible. If they are too high, that is what
: you were told about "sending signal back to radio" If the antenna/coax
: setup will not allow all of your signal to get out, it will feed back
: through your final transistor and eventually burn it up.

More mythology. What happens with a poor match is that the transmitter
cannot load into the coax with the efficiency for which it is designed.
The result is that the finals overheat.

: Usually to correct SWR you have to either change the length of coax or
: "trim" the antenna. How much depends on how far you're off. I'd find a
: shop and let them make that determination.

Changing the coax length accomplishes nothing as far as the SWR. The only
way to correct SWR problems is by tuning the antenna.

: Also, the length of your antenna doesn't the slightest thing to do with
: range as far as a mobile radio is concearned. Just make sure your radio is
: throwing all it'll throw and your ratio is as flat as it'll get and you'll
: be heard.

Again, you are wrong. In general, the longer the antenna, the further it
will transmit - and the better it will receive. This is not precisely
correct, because the radiation angle has to be taken into consideration
as well.

Close, but not right. The matching section needs to be half way between
the impedance of the coax and the antenna.

In other words, to match 50 ohm coax to a 100 ohm antenna, you would use
70 ohm coax for the matching section.

If there are currents on the outside of the coax - there shouldn't be, but
often are on poor installations - then the coax is acting as part of the
antenna system.

In this case, a tuned length of coax might make a slight difference in
the indicated SWR. It does NOT affect the actual SWR, as you note.

> 70 ohm coax for the matching section.

70 is not half way between 50 and 100; 75 is.
However, you would want 70 ohms in this instance (actually 70.71).
James is right.

Here's where you go wrong. There is no guarantee or likelihood that eighteen feet of coax will "minimize the negative effects of coax currents." You cannot say that the current drops to zero at eighteen feet. This is a claim that you are pulling out of your ass.

2000. Re: 400 amp power supply help

Newsgroup: rec.radio.cb
Date: 2000-08-17 00:00:00 UTC
From: Cory Papenfuss <papenfus@juneau.ece.uiuc.edu>
Message-ID: <yTVm5.1151$9N1.19423@vixen.cso.uiuc.edu>
Source record: 48507

Trying to build a 400amp 20V supply (8 kW!) will require at least
a 40 amp service on the 240V input. Trying to build a supply like this
out of linear components and getting a resonably well-filtered output is
not going to be easy. Since classical linear supplies have current spikes
through the diode bride inversely proportional to the ripple voltage,
these will be some *huge*, expensive diodes and some BFC's!
For this much power, I'd seriously think about building a DC-DC
converter (switchmode supply). Take a look through some books or online
for a Buck converter, or better yet a forward converter. It can operate
at much higher frequencies, so the transformers you need are much smaller.
Also less ripple, less error, better power factor, more efficient, etc,
etc.

If you are really serious about the linear supply, you need some
actual specs on what sort of allowable ripple voltage you can tolerate.

Cheers,
-Cory

Panther sells a kit that may do what you want for $49.95. Quoteing from their webb site (panther-electronics.com).

"This excellent kit for 10 meter and export SSB radios greatly improves receive sensitivity and channel selectivity in many popular 10 meter and Export radios. Kit includes a low noise, high gain transistor for improved amplification of weak signals with less noise. Two Schottky barrier diodes are used to greatly improve AM detection. I have chosen the CBC Int'ls Channel Guardï¿½ along with Panther's Peizo-Electric Ceramic Filter to improve selectivity. Detailed instructions are included with each kit. (Specify radio when ordering)"

BTW I have never done business with panther, so I have knowledge of the quality of their products one way or the other. I just happened to see this when looking through their webb site the other day.

I see you are beholding to Hams just because they're Hams? Who brainwashed you?

>As for the choke... you chose to skew the facts to "prove" your point... The LENGTH of the coax
>doesn't matter. The fact that it is coiled DOES.

Wrong again. If I can find the reference to coiling coax then I will post it.

Coiling coax DOES NOT create a choke for the normal RF currents within. Only what's on the outside.

>At any rate, you can go on thinking what you want,

You got that right. I suppose you think electrons flow from negative to positive too.

>installed antenna has a better SWR than it really does. It doesn't help a bad antenna radiate RF
>any better, and it "sure as the Devil's tail is hot" (to quote my Pawpaw) doesn't fix the problem.

So you agree. It's about time. The coax length can change the load
that the radio sees. You just said that and didn't even realize it..
Thank you.

PS The reading that a swr meter reads at the radio end is not a
fictitious reading as far as what the radio sees. Therefore coax
length can be considered a factor when optimizing a system.

>Much better to tune the antenna, get it right, and be able to "get out", than to fool your radio.

I don't disagree, but this is not what the discussion is about.

>But, again, if the antenna is proplerly set up and tuned, coax length does not matter.

I don't disagree, but this is not what the discussion is about.

>So I'll say it again.... If your SWR changes when you put different lengths of coax in the system,
>then you needed to replace the coax anyway, and/or your antenna is seriously out of whack...

Or you are using an imperfect antenna. A mobile antenna that attempt
to use the car body as a counterpoise and is suppose to magically
de-couple itself completely from the coax.

Good luck on accomplishing this with every installation.

>One more thing... Know what the difference is between ignorance and stupidity? The Igorant simply
>don't know. The Stupid don't want to, or incapable of learning.

2013. New Mobile CB Purchase

Newsgroup: rec.radio.cb
Date: 2000-08-17 00:00:00 UTC
From: nick250@aol.com
Message-ID: <20000817161405.04215.00000117@ng-fi1.aol.com>
Source record: 48520

All opinions and experiences with the products mentioned below are encouraged. If you know of what you believe to be a superior product, tell me about it. Your feedback, pro or con on the two finalist in my choice of a new radio and antenna will be appriciated. These are radios sold by Exportradios. Thanks in advance.

Radio Choice 1: This is a new Texas Ranger CB, model TR966. AM & SSB, Dual Finals. "High Power" tuned by exportradios 12 watts rms 45 peak. Ruggedly built with the trucker in mind, 2 year warranty.... yadddaaa yaddda yaddda. $219.99.

Radio Choice 2: President Grant model made by President Electronics. Export version, turbo tuned by exportradios "50 + watts". $289.99

The use of the radio will be 90% CH19 on the highway, 10% playing around on side band. I want a quality, well designed, good performing radio. And since I hope to keep it 5 to 10 years, $100 one way or the other is not the issue.

Antenna Choice. I need a mag mount to move between various vehicles. From what I read, Wilson 1000 or 5000 seems to be the way to go (am currently using a 12 year old K40 which has served pretty well). Ordinarily I would just go with the 5000 because its should be the "better one." The thing that is a bit confusing is that all of Wilsons advertising uses test results of the 1000 to compare with its compatition to demostrate superior performance. No mention of the 5000 is made in these comparisons. Could it be that unless one needs their antenna to handle really high power (which the 5000 is designed to do), the 1000 actually the better performing antenna?

Thanks again and blast away. Nick

Well I started this mess and still don't know what a swing mod is. Here is what I got from a guy on the radio. Find the end of the coil that goes to the base of the final transistor and disconnect it from ground. put in a diode that connects from the coil to ground. He was not sure which way it went. Put an electrolytic capacitor across the diode. Now peak out the radio for best swing using a peak reading watt meter. There were a lot of things the guy was not sure of. Is this right?

Here we go again! :-)
It's a myth that's hard to debunk when the true believers can call up so many examples of seeing a change in SWR with varying lengths of coax... but because their meters read both voltage and current, they're being fooled into thinking it's about coax length.
But in reality, NOTHING could be further from the truth.
Tune the ANTENNA to resonance, not the feedline.
It's in every decent book and magazine article on antennas, you'll find that RULE everywhere you look.
Linus

I though maybe this was like super modulation. AM BCB stations used to use this
to legally overmodulate the transmitters a little bit.

Or ....you are using an imperfect antenna. A mobile antenna
that attempts to use the cars body as a counterpoise and is suppose to
magically de-couple itself completely from the coax.

If we know that a mobile antenna can cause outside currents to flow
then why not consider coax length?

Using the shortest piece possible has no real advantage. If we
know that a two foot piece of coax has .000001 percent loss, and
a twenty five foot piece has .00001 percent loss then why even
consider using the short piece as justifiable from a loss standpoint?
Both pieces basically have the same loss, unmeasurable.

But we still have to figure out where to snip the coax before we put
the ends on. Why not make the length a length that could be
justifiable. Eighteen feet can accomplish this in respect to its
treatment of outside currents on the line.

>

I am talking about imperfect antennas, like a mobile antenna that can
cause outside currents to flow on the coax. If this outside current is
not choked off or tuned out then it can effect the swr reading at the
radio

When currents are induced on to a piece of coax voltage peaks and
valleys can be measured at different places along the length. If this
length is 18 feet a voltage null should occur at the radio end. This
is a good occurrence, not a bad one.

>Show us the why.....

Because using the shortest piece possible has no real benefit.

Choosing a 18 foot length can because mobile antennas depend
upon the cars body as the counterpoise. This is NOT an ideal
counterpoise and because of this can often cause currents to flow on
the outside of the coax. RF is not smart enough to figure out what
conductive material should be used to complete the antenna, so it may
use, or partially use the coax as the counterpoise. If this occurs,
and it does to one degree or another, you can cancel the effects of
these currents as far as the radio goes. Just as a choke can cancel
outside currents and be used beneficially so can a "tuned" line.

As far as a partially de-coupled mobile antenna, voltage peaks and
valleys occur at different lengths along the line. An eighteen foot
piece should put a voltage null at the radio. This is a good thing,
not a bad thing.

You don't use velocity factors for parallel antenna currents. You use
common sense and plot voltage nulls and valleys along the line.

Not you again.

There is more of a good reason to use 18 feet than to use the shortest
piece possible.

If the mobile antenna does not fully de-couple itself then it will,
or can use the coax as its counterpoise. To one degree or another
this can occur. When it does you can make a general statement that
a voltage null takes place at approximately 18 feet.

IF they are reputable & professional they will (should have 3 weeks ago) furnish you with the UPS tracking # that EVERY UPS package has when it is shipped. You can then call 1-800-PICK-UPS & using the tracking # verify that it is indeed lost with UPS, UPS can even tell you what day it was (supposedly) picked up for delivery. It shouldn't take this long to refund/replace the lost item......

Tnom,

May I ask a respectful question? But first, a little background. I run a multi-band HF antenna with which I work many different frequencies. The antenna itself is called a "screwdriver" because it uses a Skil screwdriver within the base section to move the coil up and down within the lower mast to resonate the antenna. By pressing a switch in the car, I can move this coil up/down without getting out to retune, or change whips, or any of the other usual things which would have to be done if it were not semi-automatic. The coax from the radio to my amateur amp is about 2 1/2 feet long, and the coax from the amp to the antenna is about 13". To tune the antenna to frequency, I keep an MFJ Analyzer in the front seat with me connected to the antenna thru a coax changeover relay which I also activate with a switch. This arrangement gives me an average SWR of 1.2 to 1 thru out all bands. Using your theory about coax length, I would have to have about 8-10 different coax runs in the vehicle ranging from about 130 feet to about 18' in order to operate at the different frequencies. Yet, I have tested the antenna resonance at every band I operate in both from the "remote" position of the Analyzer to right at the antenna. The results are the same at both ends.

I am not trying to be disagreeable, but it would seem to refute the necessity for cutting coax to certain lengths, and my antenna installations are quite successful--both base and mobile. So, again, if the coax length thing were true, how is it I can operate from 3.7 MHZ to 54 MHZ with this "odd" length of coax?

73

No you don't. When using a multiple frequency antenna you ignore
the 18 foot suggestion.

I can too. It doesn't relate to the suggestion by me of choosing a
18 foot length for 27mhz if you want to reduce the possibility of
problems.

We HAVE to choose a length anyways. Why not attempt to
choose a length that COULD be of benefit to you. Notice I
said COULD. If your antenna completely de-couples then
ignore the 18 feet. If not, then why would you want to ignore
it?

Well, that's about the most bass-ackwards thinking I've ever seen...

Let's explain it this way.

REAL WORLD experiments have proven that coax length does not matter. I've conducted at least 50 of these myself, to prove it to myself. RE my story about the $100 bet in this thread...

You seem to be thinking in DC. RF is an AC (yeah, that's right. Alternating Current) signal. At 18 feet, within the coax, the wave has risen from baseline to peak, then back to baseline. At 36 feet it's gone below the baseline to valley, then back to baseline. All this in the space of nanoseconds...

Ok... So at 18 feet, your coax is 1/2 wave... Great. What does that get you? Absolutely NOTHING. I'll explain why. Coax is made up of 2 conductive elements. The center conductor and the shield. If the connectors on the ends of the coax were properly made, any length of coax will show near 0 ohms resistance from shield to shield, and from center to center. The resistance obviously will go up as coax length increases, because even copper wire resists the flow of current.

Ok, having said that, we now come back to the 1/2 wavelength at the end of 18 feet of coax... Ok, great, the current (not the voltage) is at 0 at this point. So what? The antenna doesn't care, and neither does the radio. A properly tuned antenna will radiate what energy it can whether the current is at 0 or at peak when you first key the radio. The coax doesn't radiate anything, or rather it shouldn't be radiating anything.

If your SWR changes due to coax length, then one of two things are happening... Either your coax is radiating energy, in which case it needs to be replaced, because it's damaged, -or- your antenna isn't working properly (which can be caused by umpteen gazillion things that are far beyond the scope of this newsgroup.)

So what it boils down to is this: If you don't believe coax length doesn't matter, and you want to prove it to yourself, go out and get yourself a piece of coax made that goes from your antenna straight to your radio. Test the SWR on 1, 20, and 40 with an accurate (not radio shack or the one in your radio) SWR meter. Write these numbers down. Now put the

shortest possible coax between your antenna and your radio in the system, and test the SWR again on 1, 20 and 40. Did they change? If so, you need to take a look at your antenna... a SERIOUS look, because something is wrong there.

Also note, if you're using 18 feet of coax to go 8 or 9 feet, and you coil the coax up neatly and hide it somewhere, you've basically created an RF choke, which will affect your SWR reading at the radio. That's what's referred to as a UM (User Malfunction).

So try that little experiment, and if you're brave enough, post the results here to this thread.

Or remain ignorant. It's up to you.

Les:

Thanks for this. You pointed out a couple of things I hadn't thought of, whch will probably make a big difference where the installation is concerned.

I'm still churning it about in my mind. It will get built sometime in the next couple of months, and we'll see how it goes.

>again on 1, 20 and 40. Did they change? If so, you need to take a look at your antenna...
>a SERIOUS look, because something is wrong there.

It's been shown many times that a mobile coax length can effect a SWR
reading. To bad you can't look at the whole picture of an imperfect
world with imperfect antennas.

>Also note, if you're using 18 feet of coax to go 8 or 9 feet, and you coil the coax up
>neatly and hide it somewhere, you've basically created an RF choke, which will affect your
>SWR reading at the radio. That's what's referred to as a UM (User Malfunction).

You do not create a choke for the normal current flow in the coax. You
only create a choke for the external current. Could this be another
admission by yourself on how coax can effect a SWR reading??????

>So try that little experiment, and if you're brave enough, post the results here to this
>thread.
>
>Or remain ignorant. It's up to you.
>
>-SSB

You can use any length you want. I'll use a specific length for
specific reasons.

An electrical half wave of coax is approximately 12 feet (depending on insulator and conductor size, but this is the norm).

So, use multiples of 12 feet if you want an impedance mirror.

However, the best way is to measure your SWR at the base of the antenna, then tune that for minimum SWR. Then you can use whatever length of coax you want.

Ah, you're thinking of the 524 set. Yes, when you change the channel, you heard the antenna mount ca-chunking away to the next level of freq.'s. Sort of like a little mini-machine gun in your base. Or when a kid plays with those spring door stoppers, type of sound inside.

But the ant. I have is maybe 1/2" thick near the base and about 1/4" up top. Measures 'very' approximate. ;-)

He also did a new input circuit that wasn't used because the gain went through the roof.

It seems a variation of that input circuit might have been what Danny was using on the Mo Watts boxes, too.

Source record: 48560

Ed, both Doc and CitySlicker are both right. Check out the TSB from Ford. If this does not work add Doc suggestion. As for ceramic or mica capacitor, as long as the rated voltage well exceeds the circuit, in this case a 12V fuel pump line, you can any capacitor. It was very common in the 1970's to use 1000WVDC ceramic capacitor in 12V or less solid state circuits. Why? Because they were everywhere and cheaper the the low voltage ones. As for electrolytic capacitors, these do have a maximum WVDC, but also a minimum voltage to "form up". Usually about 10% of the WVDC. So a 400V cap needs about 40V to work properly and would not be good in a 12V car with a few exceptions. A 50V (very common) cap needs about 5V so is almost perfect for a 12V car. These are very common on the high end auto stereo system, you know, the ones that go BOOM BOOM BOOM a block away. Good luck. I guess I am luckly, my Ranger noise level seems manageable.

Well, like others who have been brainwashed, you apparently won't open your mind to the
truth.
Ask this same question on rec.radio.amateur.antenna, and see what the HAMs have to say..
You'll
get the same answer I just gave you. Feedline length doesn't matter.

As for the choke... you chose to skew the facts to "prove" your point... The LENGTH of the coax
doesn't matter. The fact that it is coiled DOES.

At any rate, you can go on thinking what you want, but do us all a favor and quit spreading wives tales.

2055. Re: 400 amp power supply help

Newsgroup: rec.radio.cb
Date: 2000-08-17 00:00:00 UTC
From: WB3KUM/9 <breedend@NO.excite.SPAM.com>
Message-ID: <399BD26C.EDC04A6C@NO.excite.SPAM.com>
Source record: 48562

An OLD rule of thumb was 1000mfd per amp for a half wave rectified 60 cycle AC feed, full wave wound be less. So, assuming 400 amps half wave 60 cycles times .001 farads is .4 farads, so one 1 farad cap should be fine. If you go full wave even better.

G SEVEN wrote:

for mobile operation you want no more and no less then 18 ft of Cable (50 ohm). 12 ft is way to short. you would use it in multiples of 3 ft. Also the 11 meter wave is NOT 11 meters in Diameter. I think 2 people should recheck a few things about antennas.

And what nether region did you pull THAT one from, Brad?

Wavelength isn't a measure of the "diameter" of a wave..... it's the measure of the length in space that the wave rises from baseline to peak, back to baseline, to valley, and back to baseline. 27 Mhz does that in just about 11 meters.

Would you please quit trying to confuse people with this drivel? It's not really appreciated, and frankly, I can prove you wrong on the coax... I'll even bet you a C-note on it.

Just one more thing... yes, I differ with antenna manufacturers, as do most HAM radio operators,
and alot of CB'ers who know what they are doing....

The only thing having 18' of coax MIGHT do is fool the radio into thinking a poorly tuned and/or
installed antenna has a better SWR than it really does. It doesn't help a bad antenna radiate RF
any better, and it "sure as the Devil's tail is hot" (to quote my Pawpaw) doesn't fix the problem.

Much better to tune the antenna, get it right, and be able to "get out", than to fool your radio.

But, again, if the antenna is proplerly set up and tuned, coax length does not matter.

So I'll say it again.... If your SWR changes when you put different lengths of coax in the system,
then you needed to replace the coax anyway, and/or your antenna is seriously out of whack...

One more thing... Know what the difference is between ignorance and stupidity? The Igorant simply
don't know. The Stupid don't want to, or incapable of learning.

Trim my coax? LOL That's extremely funny!!! If I trimmed my coax I would have to remove a section of my Jeep too as the cable is fit to length. either that or mount the whip to my console... after cutting a hole in my top to employ it.

I'm going to either cut down the whip to 102 or buy one. For now, the cut would work as fundage is somewhat limited. Gee, if antenna length is a factor, I guess the military is way out of the ball park on their vehicle kits too. 12' fiberglass whips are BAD. And home stations could just use a magnetic mount car antenna and slap 'er onto the rain gutter and still get awesome range.

2063. LAFAYETTE COMSTAT 25 - need manual/schematic and top cover

Newsgroup: rec.radio.cb
Date: 2000-08-17 00:00:00 UTC
From: k5dh@raytheon.com

Hi, vintage CB fans...

I am restoring a Lafayette Comstat 25 (early model, significantly different electrically from the later Comstat 25A, 25B, etc). I need the owner's manual, service manual, and schematic. Also need a top cover, which can come from a Comstat 25, 25A, or 23, as well as from other makes/models (Robyn T-123 or Teaberry Model T would certainly work, and I'm sure there are others).

73,
Dean, K5DH

The purpose of the SO239 connector is that if the antenna breaks, or fails for some reason, it is easy to disconnect it from the choke coil and reattach another. If you don't mind cutting and soldering coax, then you can save some money and attach the wires directly to the coax. Just remember to strain relieve everything. If you want pictures and ideas on any of this, go to the library and look in the ARRL handbooks, or look at AC6V's page on antennas to find all kinds of info.

If changing the length of the coax is changing the load the transmitter sees then you have something really wrong. If the coax and antenna feed point are matched the length of the coax will have no effect on swr or the load the transmitter sees.

You should run for president.. you can talk a lot and say little.. you still didn't explain how a specific length of coax affects SWR. We all know that as you increase the length of coax that you experience loss in the signal (don't neccessarily increase SWR though).. but how do you propose that one certian length, or a multiple, is appropriate and how it affects coax? If you say my coax should be 18' long and I make it 17' long, are you saying my SWR's are going to change.. I don't think it will... I use 50' lengths of coax, then various jumpers from my SWR meter and amp to the radio.. I might have 56' - 60' of coax from the back of the radio to the antenna.. and my SWR's are fine.

Coiling up the coax forms a choke for the currents that flow on the outside of the shield, but
not the currents on the center conductor.

Just curious if anyone has an ideas, theories, or suggestions on what my problem might be or how I could fix it. The thing is this, I recently bought a Pyramid PS-21KX power supply (18 amps continuous 20 amp surge I believe). Anyway here is my problem, if it could be called that. When turned on the power supply works great, gives out whatever is necessary. (never usually more than 8 amps). However when I shut it off...it is fine until after about 5 or 10 seconds...the protection light comes on then slowly dims out over the course of a minute. Is it supposed to do this? I mean it works fine, it turns on fine after it goes through that and even while it goes through it. If I turn it off and then right back on there is no problems. But I was curious is it supposed to do this, or is something wrong? And if so can it be corrected?
I have gotten good answers from you all in the past hope someone can shed some light for me. Thanks.

There is nothing wrong with it. When you shut it down it bleeds the energy out of the filter capacitors that is in the supply. When you get down to low the Red protection light comes on. Nothing to worry about. The only time you need to worry about the red protection light is if it comes on during normal operation. If you need a schematic for this supply let me know I have one.

Yes as the voltage drops after you shut it off, the protection lite will come on/ glow for a short period & then go out....this is normal on most of them..........

...Coiling the coax (in the appropriate form at the base of the antenna) will not affect the signal travelling through it (nor SWR... try it... if it affects your SWR, your antenna needs decoupling), yet will act as a choke on the signal attempting to travel back down the sheild from the antenna... a DESIRABLE effect that decouples the antenna from the coax (reducing RF in the shack).

If you are mainly going to use channel 19 try a Uniden 76 with larger driver and final done by the right person will push over 50 watts a lot less money. No SSB though and don't get into the channel kits with this radio too much money for the gain.

My experience with SSb in a mobile was a pain in the @$$. To much knob fiddling and I didn't find much activity in my area unless it was skip and then it was in Mexican which I don't speak.

If you are going to go the expanded channels SSB route the 5000 will give you a little better coverage. If its mainly highway 19 the 1000 is terrific.

Radio Choice 1: This is a new Texas Ranger CB, model TR966. AM & SSB, Dual Finals. "High Power" tuned by exportradios 12 watts rms 45 peak. Ruggedly built with the trucker in mind, 2 year warranty.... yadddaaa yaddda yaddda. $219.99.

Radio Choice 2: President Grant model made by President Electronics. Export version, turbo tuned by exportradios "50 + watts". $289.99

.....
Nick, I don't know much about the Ranger
TR 966, but I know the President Grant, Jackson and George will all fill the bill. I bought a couple used presidents that are being shipped to me now, an Original Grant DX and a George. I can't wait to get them on the air. There is nothing in the world like a clean receiver and transmit, and the President radios will give you that as well as an awesome sideband transmitter as well. There is also a receiver mod for those radios that will eliminate 5% more noise and pick up receive for at least 10%. Thats' what I want.... less garbage in my speaker and more clear signal.

here's the link for the receive mod...

(http://members.tripod.com/adm/popup/roadmap.shtml?member_name=malzev&path=cb-radio&client_ip=152.163.188.5&ts=966556141&ad_type=POPUP&id=2d4c08421c3dacd7d86a09e8bc8d7291)

Have fun! Buy the President!

Lou has also offered that schematic for free for anyone wanting to "roll their own". You can also add additional "stages" by daisy-chaining the ceramic filters. In the old days, E.F. Johnson offered cascaded ceramic filters as a stock item in their mobile CBs to achieve the same goal; narrower bandwidth of the received signal. If you go the route of daisy chaining filters it may become necessary to add a transistor stage to boost overall gain to the level of the output of the first stage in the original configuration.

Look at the outside diameter in comparison to other whips of similar length. The more surface area that a whip has for a set length will go far in determining the bandwidth. (Skin effect). Since the whip is a solid core, density has a lot to do with it also... Many of the commercial antennas (especially in the UHF region) will use solid radials rather than tubular ones for the same goal; wider bandwidth.

You can also experiment with carrier suppression and leave the modulation limiting circuit intact.

With a carrier suppression type approach, the radio is tuned for it's Max modulated output before the carrier suppresser is installed. Then the "dead key" can be set substantially lower and the loudness of the output signal is greatly increased without the modulation level exceeding 100% (in theory).

Also by not disturbing the Mod Limiter circuit there is less chance of AGC problems and failures down the lint that also rely on that circuit of feedback from it. (Case in point - Cherokee CBS-1000 / Albrecht 497)

Worth looking into, but mainly in single output AM only rigs utilizing a modulation transformer.

From: Moses <not@validemail.donotsend.net>
Message-ID: <V60n5.3306$591.264411@news.uswest.net>
Source record: 48607

I am going to be putting up an A99 on about 3 push up poles. This question has to do with the tuning rings and SWR.

Is it possible to tune this antenna while is it lower to the ground, set the rings and then hoist it up? Our would moving it higher change the SWR?

Whatever hints.. or tips for tuning this antenna would be great!

Thanks!

Moses,
Tuning it on the ground, then moving it up would be too
easy! 'Fraid it won't work that ways. Need to tune it at
the place it will be used.

Let us know how it sounds on SSB. I've been kicking around the idea about one of Exportradios.com's Turbo Tuned 2950DX or 2970DX radios but somtimes when you hot rod a radio the clarity on SSB suffers. I will not tolerate a radio that wobbles or is scratchy on SSB.

...Then when you try to run a clean amp(Messanger 4V in my case) on SSB with a radio that is doing 70 watts you suddenly have a unclean sounding station.

Who cares? At approximately 18 feet away a voltage null occurs.

I am glad you agree because if these currents can show a 3:1 reading
at the swr meter when connected at the radio, then you can bet that
your radio also sees an equivalent 3:1 ratio

>That does not mean that it affects either
>the actual SWR

Agreed

WRONG!!!! The lenght of coax does not even remotly effect SWR, Try it you'll see. However the length of coax does effect wave length. 18 foot is three qtr wavelength of coax. You would be best running a 1/4 wave antenna on a half wave (12 Foot or multiples of that). You can add cable in half waves and be pefectly safe.ie two half waves =1 full wavelenth. 18 foot is a 3/4 wavelength and is an impedence inverter to a quarter wave antenna. Think of it this way,,,, how many times does 1/4 go into 3/4? It does'nt equally, which makes it an impedence inverter. Now 1/4 will go into 1/2 waves and multiples of that evenly everytime which makes a perfect match for the quarter wave antenna. To calculate the proper wave length of cable multiply the velocity factor of the coax to a true 1/2 wave length (18 foot). ie. The vel. factor of RG8 is .66 so multiply .66 x 18 foot and you get 11.88 feet. Just round it up to 12. 12 foot is a 1/2 wave of RG 8 coax. Ant length of coax can and does show good standing waves but don't be fooled.... You will lose too much radiation off the coax instead of the antenna. What looks good,,,,ISN'T ALWAYS.

Huh ???? !!!!! ?????
Believe what you want, the length of the coax does not affect SWR
within the coax. Yes, you can purposely us coax as a matching section
and change impedance, but for all intents and purposes - as talked
about in this forum - forget it. Run what you need, no more. To
change impedances, you need to use a matching section with an impedance
of the geometric means between the radio and the antenna. In other
words, take the square root of the antenna impedance plus the radio
impdedance, and that is the impedance of the feedline you need. And the
SWR withing the matching section coax will NOT be changed. Then, yes,
the length of the section is important - but, again, not as discussed
within this forum. Radiation from the coax is NOT affected by SWR.
High radiation from coax is generally caused by feeding a balanced load
with coax (unbalanced). You can use a balun to feed a dipole, but it

is not absolutely necessary. Feeding a vertical with coax shouldn't cause radiation from the coax. A little radiation from coax will reduce you signal VERY slightly, but will not cause 'TVI', 'bleeding', or whatever. If you signal is clean, it will remain clean. You just put a bit of your power in a direction (but not a frequency) you don't need it. Check Doc's post. He is speaking the truth.

You're wrong because you don't look at the whole picture. You have
only looked so deep and refuse to believe that varying a coax length
can change the swr reading at the radio. In doing so it changes the
load that the radio is terminated in. I have explained this before.
Mobile installations are not perfect and there are things you can do
to decrease the possibility of having problems.

There is no real difference in loss between a two foot length of coax
and a twenty five foot length of coax. But we all have to make a
decision on what length to use. The argument that the shortest piece
possible is best is narrow minded thinking. It doesn't really hold
much value because the loss between a 2 and 25 foot piece is the same.
Unmeasurable. The argument that the shorter the better from a cost
standpoint makes much more sense. However the best argument for a
coax length is the length that could decrease possible problems with
imperfect installations.

All mobile installations are imperfect. All depend on the body of the
car to make the second half (counterpoise) of the antenna. All mobile
installations have to find a way to de-couple the antenna, and its
radiation from the coax.

Currents can and will flow on the outside of coax on mobile installations They can change the reading on a swr meter.Whether parallel or antenna these currents are one component of a composite load that the radio sees. This is not a measurement error since what the instrument reads is the actual swr on the line.

A way of decreasing the negative effects of current on the line is by a wise choice of coax length. Choose eighteen feet to minimize the negative effects of coax currents, or choose nine or twenty seven to increase the negative effects. At eighteen feet the voltage curve of these currents drop to zero. This zeroing can be termed nulling the cable. Nulling the cable decreases the negative effects of coax currents.

Um no, 18 ft is a half wavelength in free space. Coax slows things down so the velocity factor MUST be taken into account when calculating wavelengths in a feed line. The previous post is correct. And since the radiator of the antenna is hanging in free space, the velocity factor is nil. That is why when you calculate the length of a half wave dipole you do not take any velocity factor into consideration.

sideband wrote:
Um, no.

I hope that the following information will prove useful to you. There has been quite a bit of misinformation given mainly because of the perception that were going to use 200 watts on CB. You did not say that was your intent.

Find some 14g (16g is probably fine too) or better wire, around 19 feet worth should do. There are ideal types of wire for this purpose such as the copper clad type, but even speaker wire works very well and will last a long time. As someone else mentioned you will also need a panel mount SO239 connector. Some UV resistant rope, electrical tape and some silicone round up the rest of the materials needed. You will also need another part which works with the antenna, some RG58 cable with the proper terminations ie PL259.

Cut two pieces of wire to 8'10" long or more. Solder the end on one to the bolt hole of the panel flange on the SO239 after making sure it is looped though and twisted tightly. Solder the second wire to the centre of the SO239. Now silicone each joint to make it water tight. I should mention that the silicone is best if is not an acid cure type. Take some rope and tie it to the flange wire about one inch from the joint and the same on the centre wire. The idea here is to strain relieve the joints such that the rope is tight before the joints get pulled on. You should now have an assembly of around 17' or a little more. More is better for now.

The next detail is important as it will help reduce currents on the outside of the feed coax. The RG58 coax should have 6 - 10 turns in a coil about 6" ID near one end, then end you will connect to your antenna. You can also use RG8, but it is more expensive and harder to work with for this. Tape up the coil with electrical tape and connect it to the SO239 on your antenna and then tape up the connector after making sure it is very tight to keep out water. How much coax is left after the coil is up to you as this is where you will connect your feed coax.

Now make an eye on each end of your antenna. These are not the final eyes so just make sure they are good enough to hold things temporarily. Don't worry about the length too much but the over length should be close to 17'. I don't know how you intend to support this, but keep it away from any metal objects by at least 20'. You could hang this in a tree. Anyway attach the support rope through the eye on the centre wire and haul it up to the operating height. Make sure that you have some method of keeping it straight like a bungy cord to something below, or a sand bag etc.... Also make sure that the feed coax and choke coil point straight out at right angles or as close to possible for as far as you can manage. Connect to your SWR meter and radio.

I am assuming that you know how to use an SWR meter. If you do not, then read up. Starting at the bottom frequency of interest and working up the highest frequency of interest, make note of each SWR reading. If the SWR minimum is not within your band, then you will probably need to trim. If the SWR keeps falling as you go up in frequency them go outside, shorten both ends by an inch and retest. If the SWR starts lower and keeps rising, then lengthen each end and retest. Hopefully there is enough extra wires in the eyes to do this. Once a test run show the SWR reaching a minimum in the band the next step is easier.

Divide the frequency of SWR minimum by the desired centre frequency band of interest and multiply the result by the existing length of the antenna to find the correct length needed. Go out and make the "final" adjustment to match this length. Check your SWR one last time of course to make sure.

And there you have it. A simple dipole. Maybe not the best dipole, maybe not the most efficient antenna, but you made it. There are many other aspects of antenna installation that I will not go into here like safety and grounding, but the library should be of great use here and I recommend that you do some real research into these other aspects before installing any antenna. I don't want to be responsible for any more accidents. None of the above is new stuff, just a rehash of many articles and instructions from the past. Have fun and don't worry about perfection too much.

: How about remote mounting the antenna for the field strength meter outside
: and monitoring it from the shack?

That could be done. The Bird wattmeter has the capability of remote
location of the sensor section. But you need a conversion chart to
figure out the SWR.

I have never worried about the actual ratio - just tuned for minimum
reflected power at the frequency where I wanted the antenna to be resonant.
This assumes that the antenna will be 50 ohms when the SWR is lowest, not
necessarily a proper assumption. But it is a quick and dirty method that
produces at least acceptable results.

If I want maximum performance, I just use a field strength meter and
don't even bother with the SWR meter.

Bull. It is a myth. The only time you need a particular length of coax
is when it is a non-50 ohm impedance matching section or is a piece acting
as a tuned stub.

Look at the Maxim MAX232 IC.

The if232c is nothing more than a level translator. It takes TTL signals
and converts them to RS-232 and vice versa.

I think Kenwood used a 1488 and 1489 transmitter and receiver chips to
accomplish the same, but the Maximum chic combines both functions in a
single chip that requires 5 external components at most. Some of the
derivatives (Max 203 if I remember correctly) require no external
components...

Hope this helps some..

Do a search on the QRZ and Hamcall sites under the radio mods section. I
think you will find a complete circuit there at on of those sites.

Because the thread was about coax extensions and mobile antennas. A
less than ideal antenna that doesn't always de-couple completely. This
is to be expected with an antenna that uses the car body as a
counterpoise.

>The use of ferrite beads,
>coaxial chokes, etc..... Decouple the antenna properly and coax length

So, if the length of the coax has nothing to do with the ability of the antenna to radiate efficiently (by your own admission and my point), and since SWR is a (the?) measure of an antennas ability to radiate energy, then, by your own admission, coax length does not affect SWR.

Thank you very much for proving my point for me.

So put a balun or a choke on the line, if you're that concerned with making up for the inefficiency of your antenna. As for me, I'd rather fix the antenna, and to hell with how much coax is out there.

2149. More CB/Antenna headaches

Newsgroup: rec.radio.cb
Date: 2000-08-18 00:00:00 UTC
From: scruit@nospam.yahoo.com
Message-ID: <399d2ffe.60359198@90.0.0.1>
Source record: 48671

Hey all,

I just installed a 3' firestik II 5/8 top-loaded antenna with trunk lip mount and 18' coax on my '95 Taurus. The mount is grounded via a 10g wire directly to the battery (which is in the trunk). The trunk lid is also grounded to the battery. The antenna is mounted in the center of the trunk at the base of the rear window. The coax is routed under the seat and the excess is zig-zagged.

The radio power is wired directly to the battery (thru a fuse) using a 10g wire, and both the ground cable and case are grounded to the body about 10" from the radio.

I tuned the firestik (replacing the cap each time I tested) in the middle of a parking lot at least 3 spaces from any cars and got an SWR of 1.9 across all 40.

My problem is... Even though the SWR never changes, I have a little red "Antenna" light on the front of my Uniden PC76XLW CB that will come on about half the times I transmit. I can't find my manual so I don't know exactly what that light means but I guess it's probably bad. That light will sometimes come on if the engine is running, but then stay off if I kill the enine and transmit without moving from that spot. Also, it is affected by heat and moisture.

Has anyone seen this before? Where should I go now to fix it?

Thanks,
Grae

Being a British guy now living in the US, I find this quite
intriguing...

Your ancestors fought a war back in the 1770s because you were sick of
paying exorbitant taxes to a government that was throusands of miles
away and was constantly imposing laws and strange new taxes as a means
of exerting control over you but not really giving you any visible
benefit.

Now let me tell you about this new group of people who are thousands
of miles away (for most), who is taking about a third of your
paychecks on taxes, is demanding that your local state government do
what they say for fear of losing funding (55mph speed limits!), and
then imposes new taxes (read my lips?) in an effort to control your
behaviour, (like smoking, driving etc) yet offers you little visible
benefit (your state and city taxes pay for you garbage collection etc)

I don't really see how the British Monarchy back then was any
different to the Federal Government of today...

Moses,
You can use a tuner, but that's not the best way to do it.
Because the 'A99' is tunable, it's 'best' to go ahead and
tune the antenna for a good SWR for two reasons. One, the
mismatch is at the antenna, and that's where it should be
corrected. Adjusting the 'tuning rings' for a good SWR is
the way to do that. Two, using a tuner will always introduce
some losses. By it's self, these losses may not be significant,
but along with any other losses in the system, it can add up
to make a differnce.

Take the ground wires off the mount and the trunk lid. Run the trunk lid ground to the body short a run as possible. Usually from one side of the hinge to the other. 3' is kind of short 5 would be better it would get the top coil higher above the roof line.

three cheers for roscoe, the oscilloscope is the only true way of seeing a fully

modulated signal. you can also see the distortion of an "overmodulated" signal.

Distortion,clipping,overmodulating,That is all I hear from everybody that says swing is bad.Not everybody runs there radios to the piomt of distortion.I do believe you can set a radio up with a greater modulation than stock by modifying the limiter circuit.The radio will still have less than 100% mod with no clipping.A radio can also be set up to swing with the mod limiter in place.Everybody is relating the swing kit to the overdriven mod.I do not see how the two are related.Am I wrong at thinking the distortion is coming from the modulation circuit and not the anplifier circuit?Why such a big debate about something that is never going to change.A c.b. operator is almost always going to run his radio to its fullest and over modulate.Only the ones that have been around will run it to sound the way it should with the mic gain set to 100% or less.

One big difference you overlooked.... we elect our government... the head of
our government doesn't become heir apparent just because of some chance
meeting of royal sperm and egg. (inbred at that)

Another.... at least the feds spend most of the taxes here instead of in
England.

>Can you use guy wire for a longwire end-fedntenna?

Yup....
If it's attached to a tower (I assume you were'nt just wanting to use some excess guy wire you had layin' around as an antenna) it will probably be directional to some extent (in the direction from the tower to the wire). Be sure to insulate the chosen guy wire from the tower and from the anchor point (you'll need insulators rated for the structural stresses they'll encounter).

NO, I have a Delta Force and to get the xtra freqs, I did not have to even
open up the radio. Mine is one of the older models.

2173. Question about mobile linears

Newsgroup: rec.radio.cb
Date: 2000-08-18 00:00:00 UTC

Hi guys....

I have a polamar 225w amp and was thinking about putting it in my truck. In realistic terms, what type of range can be expected in a mobile situation with this amp on 11meters? Is there going to be much noticeable difference? I dont want to ad any alternators or anything and this amp has a nice size amp draw,and I dont want to tax my electrical system.

I guess my goals are to have a set up that can achive a 10-20mile range with some reliability. I like a clean and mellow sound and I'm not trying to sound LOUD(ie over modulated) but looking for a distance solution.

I run a stock Cobra 148F with stock mic and a K-40.

Thanks--

it will work as long as the radio is set to transmit a 2 to 3 watt dead key. you can run it without adding anything else. the amplifier will only draw about 15 to 20 amps while in transmit. so just make sure to use it while the vehicle is running. you will get that if not a lot more when the skip rolls in.

Source record: 48698

Studio,
As far as range goes, you should expect to double your present
range. Probably more than that, but double your present range is
probably more realistic.
There are a couple of things about 'remote' mounting any
amplifier
in a vehicle. You need to make some provision for remotely turning it
on and off, and you need to run ~heavy~ power leads to the amplifier.
There's a number of ways to remotely turn an amplifier on and off.
The
simplest is probably to use a relay, and run the power switch for it
back to the dash. This power line needs to be
shielded/choked/bypassed.
The power lead to run the amplifier needs to be LARGE. A 1/4"
cable,
or welding lead makes a good one. There's more resistance (power
loss)
than you may think in about 20 feet of cable. It never hurts to have
too large of a cable, it does 'hurt' is it's too small. Running two
smaller wires instead of one large one can lead to problems (RFI), so
do it 'right' to start with. Power leads should always be run to/from
the battery. They should also be fused (both (+) and (-)). While
your
installing them, you might as well bypass them. If you don't need it,
it doesn't 'hurt', and you won't have to go back and do it later.
Good luck......
'Doc

No, you are wrong. And you missed my point.
If there are currents on the outside of your coax, a 1/2 wavelength of coax will not stop it.
You are assuming that the outside shield current goes to zero at the radio as it does with an unterminated coaxial stub or as it does at the end of an antenna element. This assumption is simply incorrect. There is no reason for these currents to go to zero. These common mode currents continue to the radio case, to your microphone cable, to your power leads and, depending on how your radio is mounted, into your car.
Your belief that these common mode currents will be zero at 1/2 wavelength up the coax are based on this incorrect assumption that they are zero at the radio. Thus, it are wrong.

Stop spreading the myths. Do us all a favor. Stop pulling these claims out of your ass.

A "voltage null at the radio" is not the desired goal and is not
what a balun creates. A balun creates a *CURRENT NULL AT THE ANTENNA*.
The balun prevents common mode currents from flowing down the outside
of the coax. This is truly a good thing but is not reproduced by
an 18 foot length of coax. Read my other post which explains why
you are wrong.

Show us where the books say a 1/2 wavelength of coax connected
to your radio will prevent these common mode currents on the
outside of the coax.

You will find it nowhere. I guarantee it.

> Go back to the books

I think you need a dose of "the books." Unlike 18 feet of coax, baluns eliminate unwanted common mode *currents* (not voltages) on the outside of the transmission line. 18 feet of coax cannot do this. Show me where the books say 1/2 wavelenght of coax connected to your radio can. See my other post to see why it does not.

Sure, but 18 feet of coax won't stop it.

> When currents are induced on to a piece of coax voltage peaks and
> valleys can be measured at different places along the length. If this
> length is 18 feet a voltage null should occur at the radio end.

Not true. Why should it? See my other post to see why it will not.

>This is a good occurrence, not a bad one

What is so good about a "voltage null" at the radio?

What you really want is a *current null* at the antenna.
You want to stop common mode currents from flowing down the
outside of the coax. 18 feet of coax does nothing to achieve this.

This type of debate comes and goes every once in a while. It really is personal preference. I run most of my radios stock. The ones that are peaked a bit are not all the way up, but I do prefer more modulation than watts out. I believe that the majority of radios sound like trash when the audio is maxed out, but then there are those that scream AND sound crystal clear when done properly. It's all in whatcha know and who ya' know.

I never said 18 feet will stop common mode currents. I only said it
could reduce the likely hood of these currents creating a higher
SWR reading at the radio.

How does "reduce the effects" become "eliminate"?

18 feet does not de-couple the antenna. It however can under
some conditions de-couple the radio from a higher than wanted
SWR reading.

SWR is not an indicator of an antenna's ability to radiate energy. A 50 ohm dummy load will give a low swr but is a poor radiator.

I doubt that you are hardly anyone else knows where RF ground is at
their installation. It isn't necessarly at ground level. Depending upon
soil conditions, RF ground can be several feet below the surface.

I have a palomar 225 mobile linear amp in my car,my car has a 75 amp alternator.It has no probs and I changed the original power wires to a 10 gauge.I get 160 am watts out of it.I also drilled out the pop rivets that hold the so 239 connectors on and used a bolt and nut with star washers.For the radio I am using it is a grant xl made by uniden.It is not clipped and tuned.The only mod done was I had the clarifier fixed so the transmit wud follow the recieve.I also know that my amp does not have the mrf 455 but has the mrf 492 transistors.I checked mine with a watt meter and swr meter and I see no backward swing,but when I hook my cobra 29 ltd classic up to it it has backward swing.this is why I left my grant stock.I will have extras put in it soon but I will leave the modulation limmiter and power stock.This way it is not a splatter box 73's de genocide the 357 magnum in north central west virginia

Huh? So if I don't want a 'higher than wanted SWR", never mind tuning the antenna just use 18 feet of coax (which 18 feet of coax is not 1/2 wavelength at 27 MHz.)

There are a number of tricks to make an antenna match the feed line to give a low swr. One is a loading coil to make a short antenna appear electrically longer and give a better match for a low swr, but the radiation effeciency my not be very good as some of the power will be wasted as heat in the coil.

Besides that, there is the velocity factor to take into account too. When I choose the length of coax, it involves connecting it at the antenna and running it to where the radio is going to be and then cutting it and then putting the connector on.

That is not what I said.

I am simply stating that under some conditions it can de-couple the
radio from a higher than wanted SWR reading. That statement is
completely independent of any other adjustment of your system.
It does not imply to not tune your antenna. Any interpretation
otherwise is the fault of the reader, not the poster.

And AM "swing" is in reference to the the change in power amplitude when modulating. Typically the carrier is 50% lower than the peak at 100% modulation. So, for exmaple, 40 watt carrier "swinging" to 80 with modulation. CB radios don't seem to follow this though. I don't know why for sure but maybe its to keep the bandwidth down so 10KHz spacing is effective.

Well, I have seen 'mods' telling us to crank on this pot and your FRS
radio's audio will be 'louder'. Everyone has a great idea, but they
forget one thing - the radio was originally designed for a purpose, and
many of the components are not designed for just 'any' modification.
Yes, you can modify some radios for out of band operation - any idea of
how wide your wideband filters are? PLLs will start becomming
unstable, eventually. Of course, you already have the idea of the
swing mod. Most of us are computer literate. What mods can you make
on a computer? Hmmm.... overclock it? Sure, but what about
stability. Over clock the memory? Same answer. Some 'mods' are good -
a better antenna for the radio, a better microphone. Same for the
computer - a bigger, faster hard drive - a new video board. However,

sooner or later you will find it will be much more effective (and possibly cheaper) just to buy a new radio or new computer. There exist some audio compressers - the ones operating at IF frequencies are quite effective. You can increase your effective signal a bit - IF YOU DON'T OVERDO IT. Same with digital photography. Gee, a sharpen filter. So you run the sharpen filter. Yup, it is sharper. Gee, run it again - and again. Looky how sharp! And a lot of noise, or artifacts, have been added to the picture. Same with the radio. A little compression or gain might help, but too much and it's splatter city. For those who suggest you will get stomped on if you don't, just buy an export radio or linear. But for heaven's sake, adjust them properly. Sure, everyone tells you how good it sounds, but what do you tell your wife when she asks you how she looks? What are you going to tell her? And what are your buddies going to likely say when you ask how your radio sounds?

468/F(Mhz) = L (feet)

468/27.405 = 17.07715 feet
468/27.185 = 17.21537 feet
468/26.965 = 17.35583 feet

It's close to 18 feet... but not quite 18 feet. So 18 feet is just a figure someone pulled out of their butt. ::shrug::

Hello Moses:

Install the antenna with metal wire type guy wires attached at the top U-bolt, on the antenna. These will act as ground plane radials, and help the antenna pattern.

Make a coil of say 6 to 8 turns, of the coax, with about a 6 inch diameter, just as the coax leaves the antenna on the mast. This will help reduce radiation on the outside surface of the coax, and reduce Television Interference or (TVI) some.

I would check the SWR while the antenna is on the mast, just before you extend the push-up mast upwards. The two aluminum rings on the antenna, are there to adjust for a minimum SWR. A99, I-Max 2000, Ringo Rangers, and Sigma 4 antennas, you will see a different SWR as the mast is raised. But not a large variation hopefully.

If you measure the SWR on channels 1, 20, and 40, and then write down the result and then raise the antenna, and measure the SWR again. This will indicate if you need to adjust the rings. Kind of a raise it up and see thing.

Jay in the Mojave

That is the 1/2 wavelenght in free space. To get the 1/2 wavelength of a piece of coax you have to multiply the approximate 17.xxx feet by the velocity factor (less than one) of the coax which will make the physical length of the coax shorter than 17.xxx ft. So sticking an 18 or 17.xxx length of coax on the system to get this null that tonm suggest isn't going to work anyway.

Tune it at the point that you can reach it - as long as its a half-wave above ground your match will be about the same when it antenna is raised - My Imax-2000 with the same matching rings went down 100KHz for the center frequency after I tuned it at 20' and pushed it back up to 45'. With these antennas you are going to have a match that is reasonable, no matter where the rings are, if you have good coax and connectors. It's just your center frequency that is changed. so get it to about 20'(2 mast sections) and tune it and then put it the rest of the way up.

So that vote I have every four years is not an election?

I think you're confusing the Monarchy with the Government. The Queen has no real powers and is just a traditional symbol of our country. If you study our history you'd see that Cromwell played a big part in the construction of what we have today, which has evolved since even the Declaration of Independence.

I think you'll find that our Government spends most of our taxes in the UK,
instead of elsewhere...which is only normal isn't it?

On the inside true...on the outside it is close to a half wave. The
stated velocity factor for a coax is for rf on the inside. rf on the
outside of the cable would have the same velocity factor as an
equivalent wire.

If your radio has a noise blanker or ANL then turn it on. If it doesn't or it doesn't help then you need to hunt down the cause of the noise. I would first make sure that the power connections to the radio are clean and solidy connected. As other people metioned, running both wires to your battery is probably the best idea. They key to noise reduction is a good ground return path. If that doesn't help then try to determine where the noise is coming from. If its a popping noise then maybe new plugs and wires for the engine would help. Make sure they are of resistor type. If it is a whirring noise that is constant, then maybe your fuel pump is giving you the noise trouble. Check with your dealer to see if there are communications upgrades available for your vehicle. If it is a whirring noise that changes with engine speed then maybe a nice big 40,000uF cap across the radio's power wires will help. But always try the easy ones first.

I believe he means inside the radio. adjust VR6 so the antenna match
warning light will be calibrated to the radio if it has been tweaked.

What do you mean by zig zagged. back and forth in the car or wrapped up.
the best thing to do is get a new connector and chop the coax off at the
length you need it. Of course now I will get based by the 18' jocks but I
have installed 30+ antennas in this fashion without any issues. Excessive
coax wrapped up will kill your match. It creates an inductor in your feed
line that can reflect your power back at the radio, thus making the red
light come on.

The normal velocity factor of coax does not apply with this
application.

Hmmm... I got it off the Uniden website, so I doubt it has been
tweaked.

>What do you mean by zig zagged. back and forth in the car or wrapped up.

I mean back and forth, instead of rolled up.

I'm still confused as to why the engine running would make the light
come on. I've been trying to call Uniden to ask them, but their tech
support phone queue is so deep you get a voice saying; "Because of the
call volume, please call back later".

More on the President , please. Please elaborate on your comparisons with the Penn antenna vs. the Wilson, fixed, roving stations, compared on different days and reconfirmed by same stations on yet another day? AM, SSB, or both? How much power were you pushing? Are the results the same when you vary output? Have you utilized more than one radio on the Penn? What type equipment (IE meters) are you using to base your comparisons on?

In my experience they come pre tuned to the middle of the band. Just put it
up and it will probably work ok.

> only fused for 20 amps.why wud u have to put big cables on a little amp it
> is not a texas star 667
> later and 73's de genocide the 357 magnum in central wv
>

I would use larger cable to run to the trunk because it lowers
resitive
losses, and that never hurts. Also, I may want to add something else
in the
future, you've already got the cable run, instead of running another
line.
It's always better to over do it to start with, than having to re-do
it later.
'Dco
PS - Theres a difference between DC and AC resistive losses. A #12
for
a foot or two has less loss than a #10 at 20 feet.

Michael Champion wrote:
>
> Can you use guy wire for a longwire end-fedntenna?

Sure. Any conductor will work. Depending on the frequency/band
you want to use it on, you will have to match the antenna to the
transmitter. Forget the balun, a random or long wire antenna is
not a 'balanced' antenna. A good ground system and a matching
coil/tuner will do a much better job.
'Doc

There will always be tinkerers modding radios to see what can be done.
And thats a good thing. And it bothers noone unless interference occurs.
Some just like to whine about legalities and are not the least concerned
with what they cry about, as long as they can play radio cop!

Hello The Game: Yeah probably.

Again shunt feed is not a taped impedance matching coil, I don't care
what the article said.

Shunt feed is when the antenna itself is shunt feed, at some distance
from the bottom. NOT A COIL

You guys can call it what you want. I feed my antenna with RF current,
not DC as in tnom's posting. Why does DC current have anything to do
with anything?

If what you say is shunt feed then why doesn't any of the CB base
antennas call the impedance matching circuits, like the A99, I-Max 2000,
MaCo V5/8, Sigma 4, Saturn, Sigma 5/8, Super Magnum, Penetrator 500, CLR
II, SCLR II,
and while your at it, why not all the beams that use a Beta Match???????
Why not all the mobile antennas?????

Because it ain't shunt feed!

Wilson even calls their Wilson 1000 a "Base Loaded Antenna" which is
what it is!

Jay in the Mojave

Classic 6 channel chrome faced rig of the early 60's. Good condition and
working.
Comes with Sams volume covering this model and Xtals for several channels.
$120

Can you imagine working at the following Company?

This company has a
little over 500 employees with the following
statistics:

- 29 have been accused of spousal abuse
- 7 have been arrested for fraud
- 19 have been accused of writing bad checks
- 117 have bankrupted at least two businesses
- 3 have been arrested for assault
- 71 cannot get a credit card due to bad credit
- 14 have been arrested on drug-related charges
- 8 have been arrested for shoplifting
- 21 are current defendants in lawsuits
- In 1998 alone, 84 were stopped for drunk
driving

Can you guess which organization this is?

Give up?
It's the 535 members of your United States
Congress. The same group that
perpetually cranks out hundreds upon hundreds of
new laws designed to
keep the rest of us in line.

There seems to be to much poor service lately. (not just export r us) it rampant all over.

Why is it that a person has to resort to a public forum like this to get anyone's attention?

I don't know about the rest of you but "sorry" just don't cut it anymore.

I got mine straight from the factory. Without having to be "peaked and tweaked", it did 40watts swing on AM, 40 straight on FM, and 70watts on SSB. On mine, it doesn't matter what the deadkey is on, it still goes to 40watts. So i did not have to "peak and tweak" it at all.

You didn't say just how high it will be ultimately--I'm presuming 25 feet. Tuning on the ground or near the ground won't work--the ground will react with the antenna. You could get it up perhaps a third of the way and get it close and then raise it to it's maximum and see if it is suitable. Anything within a quarter wavelength will react differently than at a higher point. Try to tune it for the channel you will use most often.

Export Frequency Modification Instructions: (25.165 - 29.000 Mhz.)
1. Power up the radio for a minimum of 10 seconds.
2. Turn off and remove power and antenna.
3. Remove covers. Magnum Delta Force Updates and Modifications

4. Add a 47K resistor to R509 pads. (NOTE: Not necessary on newer units)
5. Remove frequency control knob on the front panel.
6. Remove diode D555 located directly above frequency control switch.
7. Reset the CPU by shorting the two pads as shown.
8. Assemble the radio.
9. Use the (CALL) button to select bands.
To switch between channel and frequency display, press (FUNC) and press (CALL).

VARIABLE RESISTOR INFORMATION
Variable Resistor Adjustment
RV-101 AM "S" Meter
RV-102 SSB "S" Meter
RV-103 SSB Squelch
RV-104 AM Squelch
RV-106 FM Deviation
RV-107 SSB Carrier Balance
RV-108 Transmit Frequency Adjustment
RV-109 FM Repeater Tone
RV-111 RF Meter
RV-112 Q169 Final Bias Control
RV-113 Q168 Final Bias Control
RV-114 Driver Bias Control
RV-116 SSB ALC
RV-117 AM Carrier Low Power Adjustment
RV-118 AM Carrier high Power Adjustment
RV-119 AM AMC
RV-120 CW Side Tone
AM CARRIER POWER OUTPUT ADJUSTMENTS
Follow the steps below to reset or adjust the Delta Force AM carrier power output levels.

1. Remove the bottom or speaker cabinet.
2. Connect the radio to a reliable and calibrated wattmeter.
3. Rotate the front panel power control full clockwise (maximum power output setting).
4. To set maximum AM carrier level, adjust RV-118 to desired level. DO NOT' ADJUST CARRIER LEVEL OVER 10 WATTS.
5. Rotate the front panel power control full counter-clockwise (minimum power output setting).

6. To set minimum AM carrier level, adjust RV-117 to desired level.
LOWERING AM CARRIER POWER LEVEL
The stock DeltaForce has the AM carrier power level set at 4 watts minimum and 10 watts maximum. Follow the steps below to set the AM carrier power level to 1 watt minimum and 10 watts maximum.

1. Turn off the radio and disconnect from power source.
2. Remove the bottom, or speaker cabinet.
3. Locate 470 ohm resistor on the power/calibrate front panel control potentiometer.
4. Add a 220 ohm resistor across the 470 ohm resistor (solder the legs of the 220
ohm resistor to the legs of the 470 ohm resistor).
5. Reset AM carrier power output for 10 watts maximum.
See AM CARRIER POWER OUTPUT ADJUSTMENTS instruction.
DISABLING THE ALC FOR INCREASED MODULATION
Many radio operators prefer to remove the modulation-limiting transistor from their radio to increase the modulation. Follow the steps below to do this modification. NOTE: As with any radio, removing the modulation-limiting transistor in the Delta Force will increase distortion and is not recommended by the manufacturer.

1. Turn off the radio and disconnect from power source.
2. Remove the cabinets.
3. Locate and remove the Q142 transistor. This is the modulation-limiting transistor.
UNLOCKING THE CLARIFIER
Out of the box the Delta Force clarifier control tracks only receive. Follow the steps Below to have the clarifier track on both the receive and transmit.

1. Turn off radio and disconnect from power source.
2. Remove both top and bottom cabinets.
3. Locate and unsolder the diode at D176.
4. Locate and unsolder the resistor at 8244. Save this resistor for a later step.
5. Locate and unsolder the resistor at 8306. Replace 8306 with a jumper wire.
6. Locate the variable resistor at RV-108. Find the leg of RV108 that is closest to the 8244 resistor location and cut it from the circuit board.
7. Position the radio with the face towards you and the solder side of the main circuit board up.
8. Locate the 8244 circuit board pad that is closest to the front of radio. Follow this trace to the pin on the white edge connector. Take the removed resistor from 8244 (step 3) and solder one leg of the resistor to this pin. Count over 2 pins to the right (this pin should be 8 volts DC) and solder the other leg of the resistor to this +8 volt pin.
9. Turn the radio over and locate the gray wire on the clarifier front panel control potentiometer. Follow the gray wire to the 12-pin

connector and cut the gray wire by this connector.
10. Solder the gray wire to the junction of RV108 and D176. Use the hole at the junction where D176 was removed.
11. Put the front panel clarifier control in the 12 o'clock (center) position and adjust RV108 for center frequency.
IMPROVED AGC AND SELECTIVITY MODIFICATION
These modifications for the Delta Force address the following issues: Receiver overloading by strong signals Fluttering or sputtering during reception of multiple AM signals just above "S-9" signal strength Increases SSB IFAGC action to keep SSB "S" meter readings in calibration with AM "S" meter readings at 30dB Smoothes out the SSB AGC Corrects channel bleed-over problems Follow the steps below to correct the above issues:

1. Turn off the radio and disconnect from power source.
2. Remove the cabinets.
3. Locate and remove the 2.21K ohm resistor at 8188. Install (replace with) a 510 ohm resistor.
4. Locate and remove the 10uF electrolytic capacitor at C161. Install (replace with) a 33uF electrolytic capacitor.
5. On the solder side of the circuit board, locate the junction of L107 and Q124, and solder the band side of a 1N4148 diode to this junction. Locate the junction of L107 and 8196, and solder the other side of the 1N4148 diode to this junction.
6. Locate and remove the 2.2K ohm resistor at 8218. Install (replace with) a 1.2K ohm resistor.
7. Locate and remove the 100K ohm resistor at 8147. Install (replace with) a 47K ohm resistor.
8. On the solder side of' the circuit board, locate the junction of 8161, 8159, D111 and C139, and solder the band side of a 1N4148 diode to this junction. Locate the junction of 8162 and C138, and solder the other side of the 1N4148 diode to this junction.
NOTE: if the Delta Force radio is going to be used exclusively on AM and FM modes and not SSB, only steps 3, 4 and 5 are necessary. Steps 6, 7 and 8 enhance the receive on SSB.
MICROPHONE AUDIO LEVEL ADJUSTMENTS
Delta Force radios with the single echo / talkback board also feature an electret microphone. The electret microphone features an audio level adjustment control. To adjust the microphone's audio level follow the steps below:

1. Disassemble the microphone by removing the 2 screws on the back of the microphone.
2. Located on the circuit board inside the microphone is a control potentiometer. This is the electret microphone's audio level control.
3. Using a small jeweler's screwdriver, carefully rotate the potentiometer to the desired audio level. Magnum Delta Force Updates and Modifications
ECHO AUDIO DISTORTION
Distorted echo audio may be experienced with a small number of the early Delta Force radios. Only the radios that have the separate echo

and talk back boards connected by a solder strap have the potential for this problem. If you have a Delta Force radio with a single, integrated echo and talk back board, then this potential problem has been taken care of and this instruction can be disregarded. If this echo audio distortion problem is experienced follow the steps below to correct it.

1. Turn off radio and disconnect from power.
2. Remove bottom, or speaker, cabinet.
3. Locate the echo board mounted to the chassis of the radio.
4. On the solder side of the echo board locate the J1 connector. The J1 connector has the audio line coming from the talk back board.
5. Locate the gray coax line going to J1. If the shield from this gray coax line is connected to J1 then cut it at the board and insulate it to protect against possible shorts.
6. Removing of' this shield and insulating it should correct any' echo audio distortion.

ECHO BOARD ADJUSTMENTS

Located on the echo board in the Delta Force radios are some additional controls. Early Delta Force models featured a separate echo and talk back board connected together by a solder strap. All other Delta Force radios feature a single integrated echo and talk back board. Determine which type of Delta Force you have and follow the steps below to make ad adjustments. Early Delta Force Models Separate Echo and Talk Back Board Fine-Tuning for Desired Echo Sound A secondary echo volume control potentiometer is located on echo board. This control can be considered a "coarse" echo volume adjustment. Follow the steps below to achieve the desired echo sound.

1. Remove the bottom, or speaker, cabinet.
2. Locate the SVR2 potentiometer on the solder side of the echo board. Adjust this SVR2 to obtain the desired echo range.
3. To set for maximum echo effect do the following:

a) Turn the front panel echo volume control full clockwise and the front panel echo delay control full counter-clockwise.
b) Locate the microphone input jack on the side of the radio. Temporarily jumper pin 3 to pin 5 on the microphone jack.
c) Connect the radio to power and a dummy load or antenna, and turn on the radio.
d) Adjust SVR2, until a slight feedback sound is achieved. The echo board will now be set a maximum effect
e) Turn off the radio and remove the jumper from the microphone jack.
f) Turn on the radio and rotate the front panel echo delay control full clockwise and test for desired echo.

AUDIO OUTPUT LEVEL ADJUSTMENTS

An audio output level potentiometer is located on the echo board. If a low output microphone, such as an RK-56 or an Astatic 636L, is used with the Delta Force it may be necessary to adjust the audio output level potentiometer. Follow the steps below

1. Remove the bottom, or speaker, cabinet.
2. Remove the 2 screws holding the echo board to the chassis. NOTE: The 2 screws are different; the sheet metal screw used in the hole closest

to the front of the radio and the machine screw is used in the hole closest to the rear of the radio.
3. Carefully turn the echo board over and locate the SVR1 potentiometer. This is the audio output level control.
4. Adjust SVR1 to the desired output level for the microphone used.
Current Delta Force Models Single Echo and Talk Back Board
Fine-Tuning for Desired Echo Sound
A secondary echo volume control potentiometer is located on echo board. This control can be considered a "coarse" echo volume adjustment. Follow the steps below to achieve the desired echo sound.

1. Remove the bottom, or speaker, cabinet.
2. Position the radio with the front panel facing towards you and the component side of the circuit board up.
3.Located in the left hand corner (closest to the front face of the radio) of the echo/talk back board is an access hole for the SVR1 potentiometer. Using a small jeweler's screwdriver, adjust SVR1 for the desired echo sound.
4. To set for maximum echo effect do the following:
g) Turn the front panel echo volume control full clockwise and the front panel echo delay control full counter-clockwise.
h) Locate the microphone input jack on the side of the radio. Temporarily jumper pin 3 to pin 5 on the microphone jack.
i) Connect the radio to power and a dummy load or antenna, and turn on the radio.
j) Adjust SVR1, until a slight feedback sound is achieved. The echo board will now be set a maximum effect
k) Turn off the radio and remove the jumper from the microphone jack.
l) Turn on the radio and rotate the front panel echo delay control full clockwise and test for desired echo.
Audio Output Level Adjustments
An audio output level potentiometer is located on the echo board. If a low output microphone, such as an RK-56 or an Astatic 636L, is used with the Delta Force it may be necessary to adjust the audio output level potentiometer. Follow the steps below to adjust the audio output level potentiometer.

1. Remove the bottom or speaker, cabinet.
2. Position the radio with the front panel facing towards you and the component side of the circuit board up.
3. On the echo/talk back board, located between the 2 mounting screws is an access hole for the SVR2 audio output level potentiometer.
4. Using a small jeweler's screwdriver, adjust SVR2 to the desired output level for the microphone used.

: When currents are induced on to a piece of coax voltage peaks and
: valleys can be measured at different places along the length. If this
: length is 18 feet a voltage null should occur at the radio end. This
: is a good occurrence, not a bad one.

There is a simple proof that this is not true. Calculate what 1/2 wave
is in free space. It will come to approximately 18 feet. Now, that is
NOT true of any current on a conductor - and the outside of the braid of
the coax is certainly a conductor. Further, this velocity varies depending
on the diameter of the coax, whether the braid is tinned, the insulation
surrounding the braid and what is in the vicinity of the coax.

: It's been shown many times that a mobile coax length can effect a SWR
: reading. To bad you can't look at the whole picture of an imperfect
: world with imperfect antennas.

It can affect the SWR reading. That does not mean that it affects either the actual SWR or what the radio sees.

Remember that the radio only cares about the currents inside the coax - at least, as far as what it sends to the antenna. Currents on the outside of the coax may leak into the rig and cause other problems, but they will not affect the amount of power the rig is putting into the coax.

No. There is no need for an antenna tuner on CB. A tuner is used when you are in need of putting a 12 meter signal out on a 10 meter antenna for example. The 11 meter band is sufficiently narrow to permit a normal antenna to cover the full CB portion of the band without any tuning.

The 66 can have a larger final put in it.
When done correctly will get you into the mid 30's peak out put.
Try www.Uniden.com they had some refurbed 76 xlw which is the preferred
model as it has an internal swr adjustment. the weather channels are a plus.
If your in the Chicago area e-mail me and I will point you in the direction
of a Tech. He also does mail order work and is worth the effort to send your
radio to him.

In context, your statement is correct, no problem.
But, if taken out of context, (and this "wrong way
pruning" is so often a problem that that is likely)
your statement is both wrong and right. The
problem is that it does not include a reference
to the design frequency.

There's a neat "graphical" technique to eliminate the
confusion.

Take an 8 1/2 by 11 piece of note paper.
Draw a smile on it, the full width of the paper.
Label the left end of the smile with two
labels: "lower frequency" and "longer".
Label the right end of the smile with
"higher frequency" and "shorter"
Lable the center of the smile with
"lowest SWR" and "design frequency".
Then take 3 swr readings - one below,
one at, and one above the design frequency.
If they are increasing in value, they correspond
to the slope of the smile from the center toward
the right side. That tells you your antenna is
shorter than it should be. If the readings are
decreasing in value, they correspond to the
slope of the smile from the left hand toward
the center. That tells you your antenna is longer
than it should be. And if the lower frequency
swr reading and the higher frequency swr reading
are both higher than the swr reading at the design
frequency, the antenna length is just about right.
At that point, you need to narrow down the
range of frequency excursion from the design
frequency, to ensure that it - the design frequency
swr reading, is at a minimum.

well to tell you the truth, most of the african cbers are very busy
doing other important things, like killing each other, fighting wars,
catching aids, and starving to death, and after all that stuff, there
just doesn't seem to be much time to talk on a cb radio, old
chap,.....cd is out.................

18 feet is 1/2 wave in the 27 Mhz (11 meter) band...

All having 18 feet of coax does is fool the radio... it doesn't make the
antenna resonate any more efficiently.

Hrm... Just sent a modified peice of coax out to the antenna... clipped the shield and inserted an ammeter... Guess what? At 18 watts PEP on side band, no current flowed. None. Not even a single mA. 14'2" out to the antenna on the rail outside my apartment. ::shrug:: Guess that debunks that issue.

Yes you need to tune that "air-cooled resistor" at the point it will be when it is up where you want it...that is the best way.

.....Then, instead of preaching coax length as a solution to a problem that you yourself recognize as one of poor decoupling of the antenna from the feedline..... why not preach better decoupling?? The use of ferrite beads, coaxial chokes, etc..... Decouple the antenna properly and coax length does not affect SWR or antenna resonance.

Nick,

Stick to the 40 channel models. The receivers are much more
selective (able to reject adjacent channel interference) than the export
models. Buy a 148gtl or Grant LT if you like ssb, along with the best
receiver front end of any cb radio on the market. I use the 148gtl
with a digital signal processor and now I know what cb radio heaven is
all about.

Jay,

At 2 - 3 month intervals it must not have been a very big BAG. If the 2222s you're using are the epoxy-type case, find some in the metal case instead and turn down that dead key.

John,

By "11 meter mod" I take it that you mean the radio has been converted for operation in the cb band. With a proper alignment the 73 will produce 30 - 35 watts of power output. Your 73 has the cb channels in it now but it doesn't hear or talk worth a @#$%....Have the receiver aligned and tune the transmitter and everything will be alright! I am constantly amazed at how often I hear your story. Simply converting or adding the cb channels to these export radios is not going to allow the transmitter and receiver to perform optimally in the 11 meter band, since both the receiver and transmitter are aligned for 10 meter amateur operation.

Phil,

Either the Galaxy 27 or the Saliut 27.....both are takeoffs on the Avanti Sigma 4 which was a full-size 3/4 wave end-fed base vertical design. Back in the 80's I used to talk from phoenix to tucson on one of these things and as I remember, they work very well. They can be a little tricky for the novice to tune and adjust, but well worth the money and the effort.

Stupid,

If you're referring to the meter built in to the radio, did it ever dawn on you that the meter doesn't go to thirty? Understand that the meter in the radio was never meant to provide direct power readings. If you want to check up on the guys at exportradios.com (recommended) then buy yourself a decent rf power meter and quit squinting at that piece of @#$% on the front panel! As to whether or not you were screwed, any way you look at it, you're probably going to spend some more money before you figure that out. BTW, if you do see a 30 at the right end of the scale, thats for the receiver signal strength....

From: fire228@my-deja.com
Message-ID: <8nll76$ag9$1@nnrp1.deja.com>
Source record: 48823

Andrew,

No Ground Plane Antennas don't work very well in the presence of metal, hence the name "No Ground Plane Antenna"! For mounting a regular (normal) antenna, remember these three things, that is if you want the best possible performance. If not, just disregard.

#1 The antenna should be mounted on the highest spot on the vehicle. Let me see, on a pickup truck that would have to be on top of the cab!

#2 Looking out in all directions from the mount or the bottom of the antenna, there should be body metal in all directions away from the mount or the bottom of the antenna. Top of the cab!

#3 Also looking from the mount or the bottom of the antnna, there should be no body metal or object higher than the mount or the bottom of the antenna. Damn, there's that pesky cab roof again.

Remember these three things and you'll know more about the proper mounting location of mobile antennas than most of the amphetamine freaks that work in these cb shops around the country! Again, like I said before, if you don't want the best possible performance from your 2 way radio, just go ahead and mount any piece of @#$% you want down on the bumper and don't worry about it. We don't want to hear you complaining later, either.

Wrong. Just how does an electron, which carries a negative charge, get attracted to a negative
source? Electrons flow from negative to positive, your are confusing electron flow with hole
flow theory which does flow from positive to negative. The reason a positive source is positive
is because there is a lack of electrons, and a negative source is negative is because there is
an excess of electrons. Please give me a reference that states electrons flow from a positive
source to a negative source. You need to study some basic physics. If you don't even understand
the difference between negative and positive no wonder you are confused about coax lengths.

2317. FS: RCI 2970 and other equipment

Newsgroup: rec.radio.cb
Date: 2000-08-19 00:00:00 UTC
From: "John J. Gervasi" <jgervasi@bellatlantic.net>
Message-ID: <399E648F.CB270C7@bellatlantic.net>
Source record: 48828

Hello all, I am selling all of my radio and test equipment. Here is
the list:

1. One RCI 2970 10-12 Meter radio; 50W AM/FM/CW 100W SSB $225
With EC 2018 Road Noise Turbo microphone Included with radio
2. One Texas Star 1200 amplifier AM and
SSB SOLD
3. One Workman 2K Low Pass
filter SOLD
4. One 24VDC 1.5F
capacitor
SOLD
5. Two Radio Shack external
speakers $5 ea
6. One Super Penetrator mobile
antenna $20
With One 6" spring included with antenna
7. One 3 pad magnetic mount with 14' of RG8U 95%
shielded $20
8. One DAIWA Cross-Needle power/SWR meter 2KW max range $100
9. One Radio Shack 3A power
supply $25
10. One Radio Shack Frequency
counter SOLD
11. One 300 W MFJ 260C dummy
load SOLD
12. One 1.5KW MFJ 264 dummy
load $45
13. One 60A DAIWA power
supply $150
14. Assorted electronic parts in storage drawer
cabinet SOLD

All equipment is like new, REALLY. I take care of my equipment. The
radio is months old.

John

P.S. I also have a 100MHz O'scope that sometimes works and sometimes
doesn't. It looks like a power supply problem that I was too lazy to
fix and now it doesn't really matter. It is a Textronix with all
manuals. Make me an offer if interested but it will probably cost more
to ship than you may be willing to pay.

Squelch is a receiver function only. It allows stations and or noise to be blocked from getting to the audio section in the set for a more quiet operation. However... turning the squelch up too high will result in blocking the stations that you are attempting to make contact with. The squelch has to be set to a "compromise" position between hearing ambient static and blocking wanted signals.

Gee jack!
when you gonna repay me for that amp you swiped on me back in 1993?
I'm still waiting on that $150.00 you promised me OVER THE AIR, ON
THE PHONE and a handshake in person right before you left with the box.

I still want my money, and i still aim to collect!

For the rest of you out here, a little advice:
whatever you do, don't deal with this person. He cannot be trusted.
There are many people here in Arizona that still remembers who Jack Thurston is.

Just so you guys know, jack thurston ripped of a blind person (me).
Now how low is that!

I expect lots of flames over this, but it will be worth saving others from your
ripoff tactics!

Here's a quick suggestion to everyone... how about those of you who think length matters always be sure to check and change lengths... and those of you who thinks length doesn't matter don't bother with it.... after four days of this, NOTHING is getting solved and this chicken and egg discussion will NEVER end... not that I mind the arguing, makes for a pretty healthy newsgroup. =)

Here's another thing to argue about.... what do you get better range out of, standard AM with a carrier or SSB with no carrier? I'm asking because for one, I don't know, and two I'll bet we'll be on it for days. =)

well this should serve as a lesson to us all. in my opinion the only
way to buy a box is to go to a meet and then deal with guys who bring
their big boxes to sell, etc, this business of dealing with strangers
over the internet, is fraught with danger,.....cd is out.....

Hmmm... Let me rephrase that... The members of the House of Commons (MPs) are democratically elected. The government is appoojnted by the party leader from all the MPs in his party.

In much the same way as Americans don't elect the cabinet, they are appointed by the President. The only difference is that Americans can vote for the president.

But think of this; With a republican majority in the Senate and the House, and a democratic President, unless you can get a 2/3 majority to bust a president's veto, the president hold the ultimate power. Just one guy.

Given the same mounting point, what is the difference in performance between a base loaded, a center loaded, and a 102" whip.

What if the 102" whip was mounted lower so that the heights of the different antennas were the same? Which would do better then?

Also, in a pickup truck, is the pickup bed a part of the same ground plane as the cab?

I've got a trc-217 from a friend. It looks old but I can't find anything about it on Radioshacks' web page, that means probably it is very old.

I'd like to learn its power output and I think this is an FM-only device isn't it? And it seems that with its own antenna, I can listen some stations but cannot make myself heard powerful enough. 4W, the max. limit in this class would be enough I suppose for that.

And it's squelch isn't working properly. If I use it, it completely wipes out the communication, even at half turned.

Many subatomic particles exist, most are fleeting as the duration of their lives are measured in millionths of a second. 3 subatomic particles, protons, neutrons, and electrons are stable. The nature and duration of the associations between these particles lead to the physical properties of everything. Protons carry a positive charge, neutrons carry NO charge (neutral) and electrons are negatively charged at varying distances. The positive charge of a proton are counterbalanced by the electrons negative charge no matter how you say it. This is th only reason why one can say any different; an atom with the same number of protons inside with the same number of neutrons (+) orbiting becomes neutral. Anything else after this is bunk. You cannot create energy or destroy it, just change or harness it's properties. To do otherwise would require an atom smasher and that has even failed in past tests.

Yes you are correct. I am wrong on this one. I apologize.
I got my right mixed up with my left ect. ect.

Let me explain. Conventional current flow is from positive to
negative.The word "conventional" threw me. Conventional usually
means "accepted usage" or "in agreement". But in this case, if the
current flows from positive to negative it hardly seems conventional.
This is what threw me.

I have always known that the real electron flow is opposite the
conventional flow. I did not know however that "conventional" was
not conventional !

2353. Re: HELP!!! How do I stop Fuel Pump interference?

Newsgroup: rec.radio.cb

Right. If the noise goes away when the antenna is disconnected, chances are it is coming through the feedline or antenna. So, if it goes away when coax is disconnected, it is probably NOT the fuel pump.

> Before you buy.

In a pickup, if the bed is elecrically connected to the frame, as well as the cab, the ground plane is the same.

As for the rest of it, it all depends on what you want. 102" whips are viewed by most of the community as the best solution, if space is not a constraint (i.e. the height does not matter to you).

I am sorry, but you are still wrong, electrons, which carry a negative charge are attracted to a
positive source. Just how do you think a battery runs down? It is because when there is a circuit
connected to the battery, the electrons on the negative charged plates flow through the circuit and
replenish the lack of electrons on the positive plate. When there are an equal number of electrons
on each plate there is no more charge on the battery. Basic physics. After the theory of hole flow
came in to popular belief, then some would argue as to which way current flows. It depends on if you
call electron flow, WHICH FLOWS FROM NEGATIVE TO POSITIVE, as current, or if you call hole flow,
which flows from positive to negative, as current. But electrons flow from negative to positive.
This has been common knowledge for several years, I studied it back in the early 1960's.

> Before you buy.

Cowboy,
The efficiency of these three antennas are;
1.102" whip
2.Center load
3.Base load
I doubt if you could 'hear' the difference in efficiency though.
How
well the antennas were tuned would make a larger difference, I think.

If you 'lower' the 102" whip you will loose a little in
'hearability',
but again, it may not make any practical difference at all.

No matter what kind of vehicle your speaking of, ~all~ of the
vehicle
makes up the 'ground plane', or counterpoise for the antenna. If you
want
to do the intergration to see how much which part of the vehicle
contributes
to the over all 'ground', be my guest (I'm too lazy)!

Here are a few things you might think about. A 'full size' antenna
will
always out perform a 'shortened' one. One draw-back to the 102" whip
is that
it isn't real stiff, it will 'lay back' in the wind. This changes the

input impedance and the SWR. If it's tuned when standing still, it'll
be
'off' a bit when moving. The same applies to any antenna, some being
stiffer
that others and showing less change when in motion.
A 'shortened' antenna mounted as high on the vehicle as possible,
may be
'better' than a full size antenna with part of the antenna being below
the
top of the vehicle. Not because the 'shortened' antenna is 'better'
than
the full sized one, but because of how/where it's mounted. A full
sized
fibreglass antenna is 'stiffer' than a steel whip, doesn't 'lay back'
as much,
so keeps it's tune better. The draw-back is that because it is a bit
stiffer,
it will eventually break (sooner than the steel whip).
You 'pays your money and takes your choice...', just depends on
what you
think will work 'best' for you.

Connecting or disconnecting the coax only proves one thing... Is the
noise coming through the antenna/coax, or is it coming in thru a dirty
power source?

I installed the Ford Fuel Pump noise filter and the fuel pump noise
went away. Now for the ignition noise...

snip

I am wrong on this one. I apologize.
I got my right mixed up with my left ect. ect.

Let me explain. Conventional current flow is from positive to
negative.The word "conventional" threw me. Conventional usually
means "accepted usage" or "in agreement". But in this case, if the
current flows from positive to negative it hardly seems conventional.
This is what threw me.

I have always known that the real electron flow is opposite the
conventional flow. I did not know however that "conventional" was
not conventional !

A fairly long (7'-8' or so minimum) elevated coil antenna will slightly out perform a 102" whip. This is due to the elevated coil forcing more current flow up higher on the antenna mast. This not only improves line of sight characteristics of the system, but reduces system ground losses as well. This difference is more pronounced as the mounting height is lowered. Base loaded and full size 1/4 wave antennas radiate the majority from their bases (high current point). In the case of very low mounting heights the elevated coil gets as much current flow as possible up higher on the mast were it has a chance to do some good. One of the biggest mistakes I see people make with the 102 whip is to mount it on a bumper or similar type low mount. They think the long whip makes up for it. WRONG! What they have is a ton of ground loss and poor line of sight because they are radiating into the dirt. Oh boy are they happy though, because their SWR is 1 to 1 over the whole band! What these misguided souls don't understand is that the broad 1 to 1 SWR proves that they have a lot of ground loss!

The impedance of a 1/4 wave antenna over a loss less ground plane is about 36 Ohms. This equates to a SWR of 1.5 to 1. Without any matching, to get a reading of 1 to 1 you have to have 14 Ohms of resistive ground loss sneaking it's way into the system! This has the same effect as putting a 14 Ohm resistor across your feedline center pin to shield along with the antenna.

There is another reason a high grade, long, elevated coil antenna will out perform a 102 whip in the mobile setting. This is due to the mechanical properties of the 102 whip and it's tendency to lay over as you are blowing down the road. This "distortion" of the antenna greatly disrupts the radiated pattern. Some of the better "competition grade" big coil antennas like the "Monkey Mades" are constructed so as to not lay over, improving your signal underway.

Here is the correct answer: :-)
Yes, in theory it is a 50/50 chance of getting the goat, BUT, having conducted a thorough analysis of all previous programs, you would discover that the grand prize is not evenly split between doors one, two, and three, but rather, one door has a statistically higher chance of being the one selected. In other words, the buy who decides where to put what before the show will chose a door at random, or will he? He might have a subconscious preference for one number or another and witlessly select one more frequently, OR he might be looking at his own stats and see that door number one has been selected 50%, door two 30% and door three 20%, therefore it is time to put the prize in door number three to balance the odds. In this instance, you have to outwit the backstage producer and decide if he is going to put the prize in door one with 50% frequency, or door number three with 20% frequency.

Same thing applies to state lotteries where in theory all numbers have an equal chance of being selected but in practice some numbers are commonly selected while others are somehow rarely picked. Gamble with the odds or against them.

Very clean Browning eagle MKIV. Case and paint are excellent. It has
been in the closet for years,and probably needs a good once over. Was
working when it was put up. I will include a copy of the factory service

manual.
$300 plus shipping

AntennaWareHouse,
About the only part of your post that I could agree with is
that a 102" whip laying over in the wind does change it's load
characteristics. The rest, about a coil radiating 'better' than
an antenna with out a coil, is garbage.
'Doc

Hello Will Bill: Yep thats what is says in the ARRL Antenna Book, 18th Edition, page 16-14. This would be a neat set up with a motorized adjustable coil.

I'll bet ol Bob Hawk doesn't call it a shunt feed antenna! (Page16-15)

It does not say shunt feed antenna, it say: "shunt feed impedance-matching arrangement: Not shunt feed antenna.

Again shunt feed is not a taped impedance matching coil.

Shunt feed is when the antenna itself is shunt feed, at some distance from the bottom. "NOT A COIL"

You guys can call it what you want. I feed my antenna with RF current, not DC as in tnom's posting. Why does DC current have anything to do with anything?

If what you say is shunt feed then why doesn't any of the CB base antennas call the impedance matching circuits, like the A99, I-Max 2000, MaCo V5/8, Sigma 4, Saturn, Sigma 5/8, Super Magnum, Penetrator 500, CLR II, SCLR II,
and while your at it, why not all the beams that use a Beta Match???????
Why not all the mobile antennas?????

Because it ain't shunt feed!

Wilson even calls their Wilson 1000 a "Base Loaded Antenna" which is what it is!

Shunt fed can shunt a portion of a loading coil. Just look it up. It's
in the ARRL handbook.

Is the ARRL handbook wrong when it diagrams a base loaded antenna
that shunts a portion of the base loading coil to ground, and then
calls this configuration "A mobile antenna using shunt-feed matching"?

Don't count on it. The "Postal Police" have still not done anything about the rip-off artist that I sent a USPS money order to last December. I filled out their fraud form, as well as 3 others who had been taken by the same person. I provided names, aliases, addresses, first hand accounts, local persons in his area willing to help apprehend him, proof of mail tampering.................

The USPS fraud division takes the attitude "Don't tell, and we promise not to ask."

The only thing I have seen out of them is a big media hype campaign about how serious about their job they are.

Good luck, but don't count on the Postal Service's Fraud Division to investigate Mail Fraud; they are far too busy telling the world how great they are to do their job......

Unfortunately, I was on a similar show, 'Let's make a REAL deal'. It
was hosted by Rod Serling. My wife and I each got to pick a door. I
chose number 1 and my wife chose number 2. Rod revealed a goat behind
door #3; however, unfortunately, my wife and I must now decide between
door #1 and door #2. I chose 1 and my wife chose 2. Rod will NOT
allow us to choose two different doors. We must agree on one. My
question to the group is this - which of us has the greater chance of
being correct at this point (especially since we chose different doors
and were lucky enough that the car was not behind #3)?

Source record: 48910

Hello Tnom: You look it up and tell me, and the newsgroup here (thanks for the cheers from e-mail you guys) where a impedance matching coil that is taped, is now a basis for calling a antenna shunt feed.

A Shunt Feed Antenna is when the antenna itself is feed, above a physically point above the bottom grounded end.

Reference: "The Amateur Radio Vertical Handbook" by Capt. Paul H. Lee. 1984 by CQ Publishing, Library of Congress Card Number 74-83411, page 26, just next to the dirty finger prints, and coffee cup stains.

If what you say is shunt feed then why doesn't any of the CB base antennas call the impedance matching circuits, like the A99, I-Max 2000, MaCo V5/8, Sigma 4, Saturn, Sigma 5/8, Super Magnum, Penetrator 500, CLR II, SCLR II, and while your at it, why not all the beams that use a Beta Match??????? Why not all the mobile antennas?????

Because it ain't shunt feed!

Wilson even calls their Wilson 1000 a "Base Loaded Antenna" which is what it is! Look at the Wilson 1000 antenna advertisment in the last Popular Communications Magazine.

I don't think so, now your reaching. Why is it assinine? Why is it with no backbone? You didn't give any explanation here.

How come you didn't answer my question, about all the other antennas that use a similar impedance matching method, why are they not called shunt feed antennas??

Jay in the Great Mojave Desert, ...just down the road ah ways from the fillin station.

Hello Wild Bill:

There where two basic lengths of the Penetrator 500.

The earliest versions where 271 5/8 inches total length, with a effective radiator length of 259 5/8 inches. All these early Penetrator 500 antennas have a 1 1/8 inch diameter bottom vertical element length, that is 77 inches long.

The next version Penetrator was shortened to 268 3/8 inches, with a effective radiator length of 256 3/8 inches. I believe this was done to allow a better SWR at the new 40 channel CB Band. These later versions have a 1 1/8 inch diameter bottom vertical element length, that is 72 inches long.

I can send you the assembly instructions if you need them.

Doc, you spew more garbage than any other ten people on this newsgroup. Time and Time again I have seen your posts that overflow with you meager "experience". If you had read my post carefully, before you jumped to pump your ego once again by portraying the know it all, and if you had half the knowledge you pretend you do, you would have realized I set up a clear definition of a elevated coil antenna that does show a slight improvement over a 1/4 wave whip. If you don't understand the principals of current forcing as it pertains to inductors and how that can be a benefit to slightly shortened antennas, then you had better pick up a book before you dispute someone that has far more experience and knowledge than you apparently do. I suggest something simple like any ARRL antenna handbook. Try the mobile antenna section. It has a fair amount of material on the improved current distribution that results from elevated coil placement, as well as pointing out the improvement in radiation resistance that is gained, the whole key to antenna efficientcy.

If you take these properties and apply them to a antenna that is physically shortend by only a few (10-15) electrical degrees and then insert a large diameter, large conductor inductor in such a way as to force more current up the mast it will result in a higher field strength over a 1/4 wave.

No Doc, my poor old CB Dinosaur, it is you who spews the garbage. You and others like you propagate more CB wives tales than I care to remember. I generally just let your misguided posts go. I don't have time to try and straighten guys like you out anymore. I would have gave odds that someone was going to retort my post with some sage wisdom. I knew better than to answer the guys post in the first place with the verifiable facts. There is always some "expert" that's going to argue.

AntennaWareHouse,
I'm certainly no expert, but I do know garbage when I hear it. I
think that if you had really read and comprehended any basic
electicity
text, you wouldn't be saying silly things like you've been doing. If
we're talking about the same thing(1/4 wave) vertical antenna, then
the
only reason you would logically put a loading coil in it, is when you
shorten the antenna to some appreciable extent. If you do that, then
where are you getting the "7 - 8 feet minimum" for a 1/4 wavelength
antenna on 27 Mhz? That would mean that you have shortened the
antenna
by some 6-18" (a length that could be compensated for with a small
capacitive hat). The coresponding coil to compensate for this amount
of
shortening would only amount to maybe one or two turns by 3"(?)
diameter.
An absolute waste of time, and we haven't even gotten into the
inheirent
losses in a coil yet!
Silly boy, blow it at someone else... Your not even original.

Tell me Doc, have you ever heard of anyone who HAS compared
a 1/4 ss whip with a slightly shortened top or centered loaded
efficient coil design type antenna that DIDN'T find a slight gain
in the use of the modified antenna over the whip? Please name
them if you can.............

The answer is you will not find a soul because everyone who has
made this comparison, and there have been a few from this group,
have seen the light. The 1/4 ss can be beat.

If you really are interested in the truth then get off your self
appointed ......(Doc?), self proclaiming pedestal and do a comparison
yourself. Until then anything you say on this subject is based solely
on your unwillingness to find the truth. Is this unwillingness based
on a fear of admitting that you are wrong, which may in turn knock
you off your pedestal?

Hello Mike: I have been collecting them a for a few years.

Get some off E-bay, TRW swap meet, local news rag with old antennas, anywhere I can.

The ones I can't find are the Starburst 5/8 CB Base Antenna, and the first CB Antenna that Hy-Gain came out with, in 1961 or 1962 called a CLR or Golden Collinear. This CLR had a single point mount that held the main vertical element in place. This design failed a lot I am told in high winds and such, breaking the main single mount insulator. The CLR 5/8 antenna had a hairpin matching wire going up and down the vertical element about 3 feet worth, from the base of the antenna.

EC Electronics and then Hustler came out with a Antler 5/8 CB Base Antenna that looked just like the Hy-Gain CLR Collinear 5/8 antenna.

Hy-Gain went to the two point mount CLRII in 1963, due to the structural failures of the single point mount CLR antennas. Then dumped the CLRII 5/8 antennas somewhere in the early 1970's, due to the impedance matching coil, was a coil etched on a circuit board, mounted in the base insulator, that was very easily burned up by to much power.

The Hy-Gain came out with the Penetrator 500, that was a 2 point mount design, with a Beta impedance matching device that was advertised as being able to take 1500 watts. This was the best 5/8 wavelength, elevated ground plane antenna in my book.

Hello tnom: Yeah I agree with ya here, need to compare em.

I have seen way to many mobile antennas with the big coil hangin out. I have been to only one shoot out, but all the guys there had the shorter than 1/4 wl antennas with a large coil, or two.

That would be neat to compare the 102 inch stainless steel whip against the shorter coiled antennas. Say a another mobile about 1 to 2 miles away looking at a calibrated S-meter. While the transmitting vehicle uses the 102 inch whip, and then tries the competition antenna.

Then the transmitting vehicle could find a place to do a 360 degree circle, while transmitting to see the different field strength levels as compared to vehicle position. This also tell ya what position the vehicle needs to be in when competing in a shoot out.

tnom@mucks,
If you think I'm on a pedistal, you'll be the first one who thinks that!
Lets all get in the same ball park. Is this shortened antenna with the loading coil a 1/4 wave antenna? If so, then why put a loading coil in it and only shorten it 6 to 10"? That really doesn't make any sense. In that case, the coil contributes more loss from resistance than anything else.
If your talking about shortening a 5/8 wave, or something other than a 1/4 wave length antenna, and comparing it to a 1/4 wave length antenna, then your comparing apples and oranges, there isn't any comparison!
Following your lead with coils, then it follows that a large coil should be better than any vertical antenna. And if you believe that, I've got this boat for sale...
'Doc
PS - If you were talking about the "'Doc", it's a nick name. I didn't pick it, it was given to me. If that really bothers you, I suggest you learn to live with it, I have...

Hello Train: Is big Ten-4 G.I.

I put up the original Avanti Sigma 4 back in the early 80's. What a night mear, to get the SWR adjusted right. With the antenna mounted on the mast, I adjusted the Gamma Match for the lowest SWR. Then the SWR changed from acceptable to way off something like 3 to 1. TILT!!!!

After checking all the connections, dimensions, coax, coax connectors, I finally settled for something like 1.7 to 1. Not what I wanted. I have never had to compensate tune a antenna before. I adjusted the antennas gamma match, then raised the antenna up and watched the antenna drastically change from OK SWR to F.U. SWR. After 3 days fighting this Sigma 4 (dare to tune me antenna) I called Buddy sales in the San Fernando Valley Ca. to buy a Hy-Gain Penetrator 500. But they weren't made anymore.....

I have converted a few of the Sigma 4's into a 5/8 wavelength ground plane antenna. The 5/8 ground plane antennas SWR stays right where you tune it, from setting on the mast all the way down, to all he way up. Don't hear all the atmospheric noise, because the 3/4 wavelength Avanti Sigma 4 antennas main pattern is looking up into the sky, not off the horizon. And the TVI went from the CB Operator Fatmouth Hour, to regular TV programing.
The neighbors loved the 5/8 wavelength ground plane antenna.

I have one of the first Avanti Sigma 4 copies, made in France or Italy, what soft almost lawn chair quality, (soft as butter) aluminum tubing. I wouldn't use this shit for a mop handle, ain't no way I am putting that crapp on my roof as a antenna. Somebody went to a lot of effort to get this cheap shit aluminun tubing. Slide on by the desert shack here I'll make ya a good deal on a new Sigma 4.

Thanks Train, I feel much better.

Jay in the Great Mojave Desert, ...just down the road ah ways from the fillin station.

Right now the skip levels are very high. If you use the squelch to try and get rid of the noise you kill your receive capability. I don't use the squelch I prefer the RF gain you can adjust your receive better with it and you don't get the clipping that the squelch does.

You need to consider what is causing the noise if it is skip not much you can do. If it is electrical from your car fuel pump, ignition etc you have some work to do.

I think you have that comment backwards. If the noise persists with the coax disconnected then it is probably ignition related. Best way to tell if its the pump is to turn the car off radio on noise blankers off,squelch off and RF gain up. Turn the key to the first position this will energize the fuel pump and you will hear a momentary whine from the radio if the pump is causing the noise.

Not true. Hams have to be able to memorize a bunch of questions and answers.
Of course, it helps if they understand some theory as well.

There are a lot of Ham "appliance operators" and some very technically
qualified CBers.

:> You got that right. I suppose you think electrons flow from
:> negative to positive too.

Actually, they do - as can be seen in a vacuum tube. But current
(by convention) flows from positive to negative.

Wrong. When first theorized scientists believed in what you just said.
But after years of establishing more knowledge on the subject they
have come to know that they made a mistake and in reality electrons
flow from what is termed positive to negative. OOPS!!!!!

Even though they discovered this initial mistake they decided
there is no real gain in re-writing all the formulas and theories.
The reason being is that it all still works out correctly. Even if it
is all ass backward.

I found this puzzle a while back and decided it would make for a good discussion. Post your answer initially without an explanation. Then after a few days explain your answer.

In other words don't give the explanation away until most get a chance to check in with their own answer.

****

You are a contestant on "Let's Make a Deal". Monty asks you to choose one of 3 doors, and you will get whatever is behind that door as your prize. One of the doors hides a BRAND NEW CAR, and the other two each hide a BRAND NEW GOAT. You choose door number 1.

Monty then opens door number 3, revealing a charming young goat. He says to you, "Do you want to stick with your original choice, or would you like to change to door number 2?"

What should you do?

What are the odds of winning by staying with door # one?

What are the odds of winning by changing to door # two?

I made the comparison from a historical aspect... the Colonies under
self-government VS government from England of the same era... In THAT era
your Kings and Queens held FAR more than ceremonial power and during that
same era, taxes collected in the colonies were spent in England. I am
rather familiar with much of English history, including the English Navy's
rather quaint method of 'drafting' ('pressing') American sailors (among
others) into the English Navy (one of several reasons for the War of 1812
with England).

About like Bill Clinton was elected by 535 electors????

In a parliamentary system, you need someone who knows foreign policy to be the Foreign Minister, someone who knows something about money to be the Chancellor of the Exchequer (?), someone who knows the law to be Home Secretary. The guy who knows nothing but everyone agrees has to be in government is the Prime Minister. Parkinson's Law.

The correct decision is to change your choice to door number 2. This will be correct more often than staying with door number 1.

Staying with door 1 you will be correct 1 out of 3 times. Going to door 2 will be correct 2 out of 3 times.

I am afraid the arguments from this will be worse than the coax length wars.

Nick

No, I'm not going to do a comparison because I ~have~ seen one
done, and I know the outcome of such a comparison to be valid. It
wasn't done by using a mobile and changing antennas for a reading
on
a so-called calibrated "S" meter. It was done on a profesional
antenna range by people who know what they are doing. So, you
prove
to me that you can find any 'shortened' antenna that will ever do
as
well as a 'full sized' one. Don't do the mobile talking to a
station
with a 'calibrated' "S" meter garbage, do it correctly so that the
results mean some thing. Then I might believe you, but not until
you can prove it.

Again let'smake sure we are on the same page. You just referenced
a 1/4 wave whip. I referenced a 1/4 ss whip. So I'll ask again.
Some physically shortened 1/4 wave antennas CAN outperform the most
readily available full length antenna, the 1/4 wave SS whip. Do you
disagree?

A 1/4 wave ss whip may outperform a given shortened 1/4 wave antenna in some situations. in hilly areas, for example, do to the high angle of radiation. but a given shortened 1/4 whip may outperform a 1/4 wave ss whip in flat areas do to the lower angle of radiation.....I have no idea what's on the market, and haven't tested any antennas side by side, but I could see one antenna outperforming the other in one situation and vice versa.

C'mon Jack, I know you are reading this group.

I will not go away. You owe me $150.00 and
you have refused to pay.

You think others are gonna trust you after the truth gets out about you?

Some info for others in here:
Jack Thurston was a "tech" at several of the local C.B. Shops here
in Phoenix for a while during the 1980's through to about mid 1994.
He was fined by the FCC on one occasion for transmitting using
equipment that was not part 95 approved, using unnecessary
power (in excess of 1 kW) and endangerment because his transmissions
took place during a bomb threat near 35th Ave. and McDowell rd (A bomb
threat where it was understood the bomb was remote triggered by radio!).

On several other occasions, Mr. Thurston was known to have worked on
radios, only to have them fail due to improper tuning or removal of
vital circuits.
On still other occasions, Mr. Thurston accepted equipment for repair,
and then
never returned equipment after long periods of time (remember these
folks, jack?).

There have even been occurrences where Mr. Thurston even "bootlegged" on

local ham radio frequencies (specifically on 146.540 simplex 2 meters)
where
he was known by all. There are still folks running radio shops here in
town
that cringe every time his name is mentioned.

So, Mr. Jack Thurston, you can deny all you want, you can hide all you
want,
but you cannot get away from the fact that you ripped people off. so,
what's it
going to be? pay me off (and I'll go away) or put up with the fact that
because I am
here talking about you, you won't get any work done.

I'm waiting Jack.

We have them retail and wholesale to those who qualify for the pricing. All it takes is a copy of your business license and you can have all you want at the wholesale rates. Bottom line is that the X Force products are still running at the best that any amp can deliver. Never fails that someone can't stand the thought of not doing as well as someone else. With the new accessorie product lines that we have now, we are selling even to the largest distributors. Anyone can be a master distributor if they purchase the minimum 400 lot of each product. Gripe used to be that we had lower prices than all others and it was hard to compete with them. Now we have them at retail so most all dealers can make money from their sales. Maybe we need to just worry about our companies and lower the prices again and keep the market to ourselves.

Now while I commiserate with your unfortunate situation, I don't really need this sort of thing using up my bandwidth. If you have a beef with a particular somebody, you should contact a lawyer about locating and suing this person in a court of law. In other words, things like this are best held privately, by the courts, or both. Not on an internet newsgroup.

Just my two cents.

it is good advice. However, I have gone the legal route
trying to collect on equipment that I was never paid for.

Everytime I get close, he up and moves, which requires that
I pay out significant sums of money to find him again, and
start the whole legal collections process on him all over.

I just want my money. I think you can understand that.

I'll try not to overdo this, about once or twice in any given
week is abotu my limit.

Switching seems like the better choice.

The odds of winning with the first choice are only one out of three, so you're twice as likely to have picked the wrong door.

That makes it seem like you're twice as likely to switch from the wrong choice back to the right choice, so the odds of winning by switching would be two out of three?

Actually, I don't think you know what your talking about, much
less being able to perform a legitimate test on an antenna.
Personally,
I don't see any point in 'reinventing' the wheel.

2449. Re: Homebrew dipole (somewhat of a long post)

Newsgroup: rec.radio.cb
Date: 2000-08-20 00:00:00 UTC
From: Will <wcwhite@mindspring.com>
Message-ID: <399FB8A9.159A6E3A@mindspring.com>
Source record: 48963
Cross-posted to: rec.radio.cb,rec.radio.amateur.antenna

The point here is a *relative* indication of field strength. So mounting the "antenna" for the meter outside is not going to yield any new information, except perhaps if it could be installed outside the induction field of the transmitting antenna. Relative values will remain the same.

The problem with antennas for 80/75 is implicit in the shorthand. Its the only ham band that is espressed in this schizophrenic way. The change of 500 kc represents a change of almost 15 percent. That same change on 10 meters is only about 1.5 percent. This is why 80/75 antennas are so tricky to tune and so inherently narrowbanded. Find a design that works as well on 3500 as it does on 4000, tuner or no, and you have a real patent on your hands. With a 40 uH roller inductor and a pair of 750 pF caps, I doubt anything I could do with the tuner would help. Longer wires higher in the air would help.

Ron,
If you could classify one of the two antennas, 1/4 w whip or
'shortened'
1/4 w whip, as a high or low angle radiator, you might be right.
Unfortunately,
either antenna can be either a high or low radiator, and all antennas
have
both high and low angles of radiation. One of the easy ways of seeing
this
is to use one of the antenna modeling programs. You'll see that ~all~
antennas
have radiation patterns that range through almost all angles, also
you'll see
that the directional pattern isn't nearly as sharp as most people
believe they
are.

I'll have to agree with Doc... all this talk about which mobile antenna has a better angle-of-radiation is really mouse milk(insignificant). All these mobile antennas they are talking about have many angles of radiation and to say that one has more signal on the horizon is wishful thinking at best.

Hello JR: I am sure the coil does have loss. However.....

If the coil is large enough in diameter, these loss's will be kept to a minimium.

Does the coil effect the elavation angle in such a way that the energy is directed lower than a 102 inch whip 1/4 wavelength antenna? And if the elevation angle is dropped, this would more than compensate for coil loss.

So this converation is like a marble going around in a funnel, it will soon drop to the bottom. The antenna comparison tests need to be done, to get to the botton of all this.

Hello Professor:

Is your statement here from your vast knowledge of Electromagnetics, or
actual field strength comparison testing the antennas?

Or maybe the staff of the Skywave Engineers?

Or did you see this on some web site somewhere?

Maybe a Soap Box Opera?

We haven't seen you in any winners circles at any shoot outs.

It sure is amusing to see someone so sure of something, when you know
they don't know.

I have a Palomar Skipper amp .It does 0-40 watts variable & 80 watts on the high side AM. It's always worked well. Now on AM variable its fine,however on high the 20 amp PS 21K power supply 's short circuit lite goes on. It also does this on ssb either variable or high. I checked everything and know its the amp. A few questions--1) What could be the problem? 2)What are some of the best amp repair shops? 3)If I need a new amp,where can I purchase the same amp? This is a blue -faced Palomar Skipper modulator with a pre-amp. Thanks for the help.

Eucalypt Software - Makers of Autopost & Rocketfuel --- Ripped Me Off!!!
-
All potential buyers should be warned to steer clear of this company. They have a repeated pattern
of ripping people off and ignoring requests for support.
-
I know someone who sent in the $10 registration fee for Autopost TWICE (thinking the first one may
have gotten lost) and in both instances, never got a registered version of the program and all of his
emails were completely ignored.
-
I myself purchased Rocketfuel on-line and had to pull teeth to get an unlock code. The web site was very
quick to take my money, but no registration/unlock code came for days and days. I repeatedly emailed them,
only to receive nothing but autoresponses. After 5 days I sent them a message stating that if I did not have
a working version of the program by the close of business that day, that I would challenge the credit card
charge. Magically, the code arrived several hours later.
-
What kind of way to do business is that?
-
In any case, its academic... there are other products available for free that do virtually the same thing
and I only wish that I had known about them before I wasted my time with Eucalypt Software.
-
If your in need of automatic news posting software, there is nothing better than "NNTP Power Post 2000".
It's graciously been made available free from the following web site:
-
http://net-toys.8k.com/
-
Save your money... your time... and the aggravation!
-
Peace,
-
PPN
-
-
PS: I have no affiliation with the makers of PowerPost 2000.
-

It isn't illegal to own an amplifier if you hold a license that allows the use of such amplifier (an amateur radio operator's license for example). If you do not hold such a license then it is illegal to own the amplifier even if you do not use it. We discussed this recently, see the rules posted below. Note item (c).

Sec. 95.411 (CB Rule 11) May I use power amplifiers?

(a) You may not attach the following items (power amplifiers) to your certificated CB transmitter in any way:
(1) External radio frequency (RF) power amplifiers (sometimes called linears or linear amplifiers); or
(2) Any other devices which, when used with a radio transmitter as a signal source, are capable of
amplifying the signal.
(b) There are no exceptions to this rule and use of a power amplifier voids your authority to operate the
station.
(c) The FCC will presume you have used a linear or other external RF power amplifier if--
(1) It is in your possession or on your premises; and
(2) There is other evidence that you have operated your CB station with more power than allowed by CB
Rule 10, Sec. 95.410.
(d) Paragraph (b) of this section does not apply if you hold a license in another radio service which allows
you to operate an external RF power amplifier.

You are on the right track. The chances of winning before a door is open is 1 in 3. Take that a step further the likelyhood that one of the other two doors than the one you chose has the car is 2 in 3. So far pretty simple. Here is the part that some people have getting their head around. After the game show host opens one of the other doors, the likelyhood that the doors you did not choose holds the car is STILL 2 in 3 and since you know that door 3 holds a goat, then that makes door 2 a two out of three favorite to hold the car. The way its easy to go wrong here is to think this is the same as having only two doors to begin where guessing which one holds the car is a 50/50 chance. The fact that the host had to act by opening one door, and knowing that he could not open the door with the car in it gives you the extra info. In some circles they call this "the theory of restricted choice".

>Switching seems like the better choice.
>
>The odds of winning with the first choice are only one out of three, so
>you're twice as likely to have picked the wrong door.
>
>That makes it seem like you're twice as likely to switch from the wrong
>choice back to the right choice, so the odds of winning by switching
>would be two out of three?
>

Why would you want to see a website of these people that MADE a MONKEY out of you? This over priced, over rated antenna that most people don't even put 1/10th of what it allegedly can handle, has made monkeys out of hundreds. Now I don't say anything against anything that is stainless steel, but WHY have NON-stainless allen screws that hold the whip? I believe the site you are looking for is darwin.com or zoo.com ! You din't evolve from monkeys, and we shouldn't buy antennas made from them either!!!!!!
Dave!!!!!!!

NO, your warehouse is spewing more garbage when he don't like the truth! When WILL you non-DinoSORE yound whipper snappers learn that there is NOPTHING better than a 108" whip or a 102" with a spring? NO Coil. It is longer. GET OFF your wilson drugs and come back to real antenna design reality! I put my 108" on the side of the car, as high as I can put it, so it blows smoke as far as possible (and I look like da poll-leece!) ! So when you want the best, send your $$$$ to me!!!!! 1 left out of the 20 made!!!!
Dave!!!!!!!!

AntennaWareHouse wrote in message <399F3843.461949B9@cis.net>...
Doc, you spew more garbage than any other ten people on this newsgroup. Time and Time again I have seen your posts that overflow with you meager "experience". If you had read my post carefully, before you jumped to pump your ego once again by portraying the know it all, and if you had half the knowledge you pretend you do, you would have realized I set up a clear definition of a elevated coil antenna that does show a slight improvement over a 1/4 wave whip. If you don't understand the principals of current forcing as it pertains to inductors and how that can be a benefit to slightly shortened antennas, then you had better pick up a book before you dispute someone that has far more experience and knowledge than you apparently do. I suggest something simple like any ARRL antenna handbook. Try the mobile antenna section. It has a fair amount of material on the improved current distribution that results from elevated coil placement, as well as pointing out the improvement in radiation resistance that is gained, the whole key to antenna efficientcy.

If you take these properties and apply them to a antenna that is physically shortend by only a few (10-15) electrical degrees and then insert a large diameter, large conductor inductor in such a way as to force more current up the mast it will result in a higher field strength over a 1/4 wave.

No Doc, my poor old CB Dinosaur, it is you who spews the garbage. You and others like you propagate more CB wives tales than I care to remember. I generally just let your misguided posts go. I don't have time to try and straighten guys like you out anymore. I would have gave odds that someone was going to retort my post with some sage wisdom. I knew better than to answer the guys post in the first place with the verifiable facts. There is always some "expert" that's going to argue.

Dave!!!!!

Jay in the Mojave wrote in message <399FB5E3.26A158C1@qnet.com>...
Hello Professor:

Is your statement here from your vast knowledge of Electromagnetics, or
actual field strength comparison testing the antennas?

Or maybe the staff of the Skywave Engineers?

Or did you see this on some web site somewhere?

Maybe a Soap Box Opera?

We haven't seen you in any winners circles at any shoot outs.

It sure is amusing to see someone so sure of something, when you know
they don't know.

Jay in the Mojave

Electrically connected... Not really that hard to understand... If you were to take a continuity tester to the frame and box, then frame and cab, then box and cab, and they all show continuity, then it's electrically connected...

To put it simply, if you can conduct electricity thru it, it's probably electrically connected.

SSB,
I wholeheartedly agree. That is my whole point. Use whatever length it takes to get from rig to antenna, and forget about all those formulas and VF. Tune the antenna, and the rest will fall into place. The only way the coax will affect SWR/Impedance/Loss is if it is either bad or too long, in which case, you'll get loss.

It is OK to believe that coax length is important, and I won't get into a flaming match over it. All is well on the Western Front. LOL!

Yes, by keeping the ohmic losses in the coil to a minimum help keep power losses down also. With the coil at the base of the antenna, the voltage distribution above the coil is max and the current is minimum. By moving the coil up near the top moves the current distribution up to cover more of the length of the antenna and gives better radiation. However there are trade offs, with the coil at the base it sees the entire capacity of the antenna, as the coil is moved further up it sees less of the capacity of the antenna and therefore the coil must be increasingly larger to resonate the antenna. So you can reach a point where because of increasing the size of the coil, gain in radiation is offset by the increase in coil losses.

Hi, I`m looking for Blutarsky. I`m told he hangs out here sometimes.
He has once more wandered away from the group home.
Without his medication, he is at risk of injuring himself or others.
Thanks in advance.

>playing radio cop.
>

I for one am not interested in playing Radio Cop. My CB may have accidentally peaked over 4 watts from time to time... purely by accident I assure you, but saying you're going to take legal action against someone for not sending you a device that is illegal for you to operate in the first place is a bit silly. The original poster has the right idea. He's got his homeys on the island going after this guy...

Something I always wondered about a mobile antenna. Since the air flow over the car is bending the longer antennas there by presumably lowering swr, might it not be better to have a shorter no bend antenna which will maintain its rigitity and tuning in the airflow? Or perhaps compensate for the bending in the wind by making the antenna silghtly longer than it should be to produce a low swr while stationary.?

To be prosecuted for the term "POSSESSION" according to a field agent FCC friend I know, the illegal equipment must be possessed on the premisis. Now, if the person purchases the illegal item and stores it on the premisis, then there is reason to file charges. Otherwise, there is no illegality in purchasing such equipment. Sorry JR. You are wrong. SO FUCK YOU!!!

None of this says it's illegal to own a linear. According to (c) it both has to (1) be in your posession AND (inclusive. no choice here) (2) thre is other evidence......

BOTH (1) AND (2) have to be true to satisfy (c), and therefore be illegal.

Don't say you can't own it... It just says you can't get caught using it.

Just my two cents.

Isn't that the whole point? Buy low and sell high? Gee, the lasttime
I checked, Exports R Us was a retailer. And if you want something,
he's got it.

But when anyone sells anything on the newsgroups, they sell it for
whatever they please. There's no similarity between a private party
sale than a business sale. Everyone has their prices and thats that.

Supahman is back out!!!

Sorry. What I should have said was, not legal for use\sale by anyone
operating under the guidelines of the FCC regulations.
They may be some other places (countries) where they may be used/sold,
but not under FCC guidelines for operation in the US, and it's
possessions.

Certain RF power amplifiers are illegal to sell or use in the US, under
FCC rules. ANYTHING that cannot be sold legally is considered contraband
under the law. You cannot legally buy contraband, so it is illegal to buy
certain power amps for possession by regular, nonexport licensed
people/companies.
Read FCC Part 97,subpart D-97-315/97-317.

I've had good luck with the magnet mount Wilson 1000's, and a few others. It depends on the installation, SWR, coax condition, surrounding objects, local interference, etc. as to how far you can "get out" and hear.

Is it that your receive (ears) is (are) weak, or the transmit?

tnom@mucks,
I really don't see what your objection to 'old' knowledge,
if that's what you mean. A very great deal of it is still as
valid now as it was when it was 'new'. Of course, there's some
of the 'old' technology that has been 'proven' not to be as true
as it once was. The same holds true for any technology.
Electronics isn't like mechanics, a 'shade tree' 'tech'
is at a big disadvantage because electronics isn't very intuitive.
Like it or not, you have to do some reading/studying. And, like
any field of study, you have to have a good basic knowledge, a
'foundation'. Otherwise, you end up like some people, and draw
false conclusions about things, such as antennas. Just like
bolting a rear axle to the exhaust pipe makes for a crummy drive
train.
You might do a little reading about some of that 'old' technology,
you might gain a few insights in where your making mistakes. You
might also try some of the 'new' technology, such as the antenna
modeling programs. That might really open your eyes! But then,
maybe not...

NO, not really. For a super expensive and supposedly well made STAINLESS STEEL antenna, it shows the NO BRAINS of the manufacturer by NOT using stainless steel allen screws to hold the whip. The ones they use RUST and rot, making re-setting the whip impossible!

As for the Firestone tire problem, I suggest that you get yourself UNBrainwashed from the MEDIA and go down to your local Mom & Pop Non-Corporate Tire shio and ask them the REAL story. Cost has NO relation to the alleged problem.

Can someone tell me what all this means?

WASHINGTON{MB8719}

CUT TR32 Change R99 to a 2.2k resistor Change R94 to a 2.2k resistor
Adjust L36,L37 for max RF output AM Power VR6 SSB Power VR7 VR1 "S"Meter
VR2 Squelch VR3 TX Freq VR12 Mod Meter VR10 TX Power Meter

TR32 Audio limiter What happens when you cut this?

How do you adjust L36, L37 ?

I Think I understand the power settings AM VR6

Why 2 for SSb? USB & LSB ???

What is the resistor change for??

Is there a place to adjust the modulation ?

I have a Dosy Tc-4001-p Meter to do the tuneup. Thank you tommis

Doc you don't know what you are talking about. I have no problem
with new or old technology. But what I really hold in high regard is
the truth.

You obviously are stuck in this false belief. If you really really
wanted to know the truth you would seek it out directly by yourself.
You however are so closed minded that you wouldn't ever consider
making a comparison test for yourself. The proof is, and always has
been in the pudding.

Modeling programs do not show a high enough resolution and can not
be depended upon for a final answer in a comparison of two very
similar antennas in the real world. Never the less I have in the past
posted models and shown that a 102"ss whip can be beat. Even so
it means very little. You can't hang your hat on a modeling program. A
modeling program is ONLY a piece of software that never can take into
account all the real world conditions. We do live in the real world
don't we? Then go right to the horses mouth and check these antennas
out yourself.

P.S. About books and modeling programs. I would dare to say my library and use of modeling programs would dwarf yours. But in the end the whole truth is not always in a book or in a program. It's in the real world.

I heard that the plant that went on strike made the tires. Then I heard
that an engineer of theirs "blew the whistle" on them. My local tire store
said that THE MEDIA has blown this whole story out of proportion. He said
if the belts come off, it is like you are driving on the steel belts (like a
lot of us po people have already done this in the past)! It is THE HEAT
that has damaged a FEW of the tires, but mainly NAILS, CB antenna tips (cut
off when matched), and blow outs have caused most of the problem. For the
thousands of tires made, a VERY FEW have problems. WAY down south in the
heat they have area 1 to take care of first. BUT the media has everyone up
north so brainwashed, that they wished that they were area 1 to get theirs
first! I hope THE MEDIA that has blown this WAY OUT of proportion GETS
THEIR TIRES blown out because of the lies & hype they did to blow up this
story!!!!!
Dave!!!!!

Yea, I guess thats possible, but it has USUALLY been my experience that noise is coming through the antenna or line when it is removed and the noise goes away. I've seen some coax even act like an antenna picking up unwanted noise.

You might be a Yankee if... (the other side to REDNECK humor)

The sound of Fran Drescher's voice doesn't bother you.

You've watched the movie "Deliverance" and you're
afraid to go on a camping trip. Ever.

For breakfast, you'd rather have potatoes than grits.

You can name at least 4 hockey teams.

You've never eaten Okra.

You wonder why people in restaurants don't talk as loud as you do.

You have never planned your summer vacation around a gun & knife show.

You don't have any problems pronouncing "Worcestershire sauce" correctly.

You've never had grain alcohol.

You are familiar with all the rules to Lacrosse.

You have no idea what a polecat is.

You don't see anything wrong with putting a sweater on a poodle.

You've never had bangs.(ed. note - OR if you do have them,
they aren't several inches ABOVE the top of your head)

You'd rather vacation at Martha's Vineyard than Six Flags.

You don't have at least one can of WD-40 somewhere around the house.

You would rather have your son become a lawyer than
grow up to get his own TV fishing show.

You refer to two or more people as "you guys" instead of "y'all".

You think more money should go to important
scientific research at your university than to pay the salary
of the head football coach.

You prefer a bagel over a donut.

You don't know anyone with two first names (i.e. Joe
Bob, Billy Bob,Kay Bob, Bob Bob, Sara Jane)

You get freaked out when strangers in public talk to you.

None of your fur coats are made with real fur.

You don't know what a Piggly-Wiggly is.

You think NASCAR stands for the North American Society for...(something)

You eat fried chicken with a knife and fork.

Your idea of a perfect meal is "Lahbsta and Clam Chawdah."

You use the horn in your car more than once or twice a year.

Everything you know about the Civil War you learned watching TV.

You don't "reckon".

You're not "fixin" to do anything.

COLD as ICE and TWICE as NICE.. Mr. ICECOLD BIG APPLE TREES says.. It don't mean a THING if you ain't got that SWING!!!!!!!

Well, I for one wouldn't do that mod... It'll make the radio overmodulate and sound like crap.

Take it to a qualified tech to have it brought on line, and be happy with it.

You might be a Yankee if... (the other side to REDNECK humor)

The sound of Fran Drescher's voice doesn't bother you.

You've watched the movie "Deliverance" and you're
afraid to go on a camping trip. Ever.

For breakfast, you'd rather have potatoes than grits.

You can name at least 4 hockey teams.

You've never eaten Okra.

You wonder why people in restaurants don't talk as loud as you do.

You have never planned your summer vacation around a gun & knife show.

You don't have any problems pronouncing "Worcestershire sauce" correctly.

You've never had grain alcohol.

You are familiar with all the rules to Lacrosse.

You have no idea what a polecat is.

You don't see anything wrong with putting a sweater on a poodle.

You've never had bangs.(ed. note - OR if you do have them,
they aren't several inches ABOVE the top of your head)

You'd rather vacation at Martha's Vineyard than Six Flags.

You don't have at least one can of WD-40 somewhere around the house.

You would rather have your son become a lawyer than
grow up to get his own TV fishing show.

You refer to two or more people as "you guys" instead of "y'all".

You think more money should go to important
scientific research at your university than to pay the salary
of the head football coach.

You prefer a bagel over a donut.

You don't know anyone with two first names (i.e. Joe
Bob, Billy Bob,Kay Bob, Bob Bob, Sara Jane)

You get freaked out when strangers in public talk to you.

None of your fur coats are made with real fur.

You don't know what a Piggly-Wiggly is.

You think NASCAR stands for the North American Society for...(something)

You eat fried chicken with a knife and fork.

Your idea of a perfect meal is "Lahbsta and Clam Chawdah."

You use the horn in your car more than once or twice a year.

Everything you know about the Civil War you learned watching TV.

You don't "reckon".

You're not "fixin" to do anything.

COLD as ICE and TWICE as NICE.. Mr. ICECOLD BIG APPLE TREES says.. It don't
mean a THING if you ain't got that SWING!!!!!!!

Dave:

First off, yes, it is the Orthodox position, in certain circumstances. They favor the mother's life over a child's. If a pregnancy threatens a mother's life, they will end the pregnancy. I have this on authority from a jewish friend over the internet.

Secondly, equating earth religions with communism is ignorant. Communism favors people over all else. The earth religions favor harmonious symbiosis between people and nature. I have this on authority from other friends on the internet.

Third, I agree 100% that Gore shouldn't be elected. Bush isn't much better, but given the choice between these two evils, I'll pick Bush. There are bigger issues than just communications regulations out there.

Just my two cents.

This type of debate comes and goes every once in a while. It really is personal preference. I run most of my radios stock. The ones that are peaked a bit are not all the way up, but I do prefer more modulation than watts out. I believe that the majority of radios sound like trash when the audio is maxed out, but then there are those that scream AND sound crystal clear when done properly. It's all in whatcha know and who ya' know.

Hello JR: I don't know how the coil works in a quarter wave antenna. I can guess it will make the antenna look longer ect. But how it effects the current I don't know.

Perhaps a telescoping antenna with a variable coil, could be made to compare against a 102 inch whip antenna. Another thing to consider is that these antenna installations are mounted on all kinds of different vehicles in different locations.

So the 64 dollar question is: "Do you know what direction your antennas has the most field strength in, and is the coil placed in a optimum height, and is it really offering a lower elevation angle?????

Not as easy task! Sounds like a lot of field work to me, after pounding a lot of keys on Eznec.

Jay in the Mojave

Yeah a Gamma Match has series inductance and capacitance. Unterminated
coax has beed used for a gamma match.

>
> Shunt fed antennas do not run the "short" end of the antenna to ground. The

Wilson calls it base loaded verical. But the term shunt feed is a loose
one. Shunt feed impedance matching coil is one thing and shunt feed
antenna is another.

Now I for one would actually be interested in reading everyones experiences with lousy shops and techs with names named. Think it would make a great site. Plus, mistakes are a valuable learning tool and when someone else makes them that is one less you make yourself, IF you are paying attention.

Hey Dave, a question if you would. Other than the communist and junk theory, why do you have such a hard-on for Northstars? I mean, I enjoy reading your opinion (sometimes) but you always seem to jump on the (falling) star (as I like to call 'em). I have one and I don't think it is any more junk than the Galaxys I own.(or Rangers, for that matter) Sure, it drifts some, but what the hell? As far as in my top ten, I wouldn't even rate it, but whaT IS your take on this radio? For the record, I'm currently into the Tram thing.

None of my radios have mod kits. To each their own though. Equate big modulation with hate and discontent? I don't need any power to talk world wide from my locale. The only thing I can see is someone with some big modulation stepped on your head!

Doubt you'll see much argument on this one...

Watt for Watt, SSB beats AM hands down, just as CW beats AM or SSB...
CW requires less bandwidth than SSB, just as SSB requires less bandwidth
than AM... the same power but spread over a smaller area. Smaller
transmitted bandwidth means less signal has to reach the receiver on the
other end to still be intelligible.

Yeah, they always think that updating it will make it better. I never really thought that was a good policy for anything. One day it is one way, the next day it is something else. That and eBay's goddamned proxy bid thing is the most unfair policy in the world. Don't get me started on their radio regulations.....

Actually, if you can find the ALC control (one of those I think, if you can't I have the instructions somewhere around here for it) you can turn that up a bit but I would leave the thing alone. I have one with a D104 and it is fine without any mods. All I did was turn the ALC up (A little too sometimes but that is what mic gain is for) since it wasn't doing squat on SSB and the thing is fine. I did cut the limiter once and as the other poster said, it sounded like crap.

2593. Cobra 2000 problem.

Newsgroup: rec.radio.cb
Date: 2000-08-20 00:00:00 UTC
From: sideband <sideband@cac.net>
Message-ID: <39A0914E.D6C3F086@cac.net>
Source record: 49107

Ok. It's finally happened, and, without a reputable tech in the area, I need to find help for this elsewhere.

Cobra 2000 transmits just fine on AM.
Sideband, however, my favorite mode, is where the problems are... When I key on LSB or USB, all I get is a big SQUEEEEEEEEEEAL. If I talk into the mic, I can just barely hear what I'm saying on another receiver in the house, but it's scratchy, and the squeal stays.... but here's the kicker... The squeel, causing the transmitter to go full tilt (All 18 watts PEP) causes the radio to BACKSWING from full tilt back to about 16 or 15 watts.

As I said, the radio behaves normally on AM. Sounds as clean as ever, so I don't think it's the audio section. Maybe the balance modulator? Maybe the carrier's not being shut off in sideband? I don't know.

Has anyone run into this one before? If so, can ya point me in some direction on which components to test?

Thanks in advance.

2594. Re: Best Type of Mobile Antenna

Newsgroup: rec.radio.cb
Date: 2000-08-20 00:00:00 UTC
From: Professor <bgriffey@kwom.com>
Message-ID: <yp0o5.38225$2k1.1088074@news-west.usenetserver.com>
Source record: 49108

We have discussed this many times... Any coil loading to a mobile antenna is
a compromise in performance compared to a full length 1/4 wavelength aerial.
There is nothing mystical about this... in fact it's really common sense
that the longer full length 1/4 wave antenna presents a larger surface for
the wave to "hit" on receive as well as a larger surface to "radiate" from.
The major reason for the loaded type CB antennas out on the market is one of
convienience. Since a 1/4 wave antenna is rather long and cumbersome at
27MHz... more people opt for the shorter... more managable antenna and
accept the degradation in overall performance.

Although the bending of the antenna in the wind changes the impedance...
it's so slight a change to be insignificant in most cases.

Be very carful with this suggestion... I have personally seen people do this
and it can have a very negative impact on the match of the antenna. By
attaching sonething to brace the antenna... you have changed the electrical
properties of the antenna. I definately don't recommend this for just this
reason. Like I said in an earlier post... the effect of the bending on the
match and radiation of the antenna is minimal and really not worth staying
awake nights thinking about...

Here we go again, Brian you so full of it.
You should stick to you're crap amp sales. There are
other antenna's that perform just as well as a 102", it
has been proven here lots of time. The decrease in
signal on a 6' antenna to an 102" is negligible, so unless
your like Brian, taking it, then size really doesn't count.

Neither hams nor cbers have an exclusive on the 'brain-challenged'.
Probably the result of excessive exposure to high power RF.

Just a quick note - a low loss vertical, properly tuned, with a good
ground, has an impedance not much over 30 ohms and will give you an SWR
of around 1.6 to 1 on 50 ohm coax.

It's not often that people admit to error in here, and you've done this
twice on the same subject, I congratulate you on being big enough to stand
up and apologise.

I often pick up either the wrong mic during a qso, and have even been known
to pick up the Key to talk into that, but I've managed to isolate the latter
problem by screwing the thing to the desk.

We all do silly things and it's more fun admitting it than having an arguement about it/or denying it.

Well done tnom@mucks.net!

Electrically connected... Not really that hard to understand... If you were to take a continuity tester to the frame and box, then frame and cab, then box and cab, and they all show continuity, then it's electrically connected...

To put it simply, if you can conduct electricity thru it, it's probably electrically connected.

> > ....thankyou very much.

Could be the unit or the antenna... If the unit has an RF Gain, try turning it up all the way, and see if it improves your range.. If it's a new radio, there's probably nothing wrong (read PROBABLY) with the tuning of it. If the RF gain doesn't fix it, then you probably need to take a look at your antenna.

What do you mean by "not much distance"? A mile? Five?

<snip>

I've often wondered why it is that people with such ideas haven't stated emperical evidence to back up their claims... If you really want to konw what would perform better between two antennas, get two of 'em.

Have a friend drive 5 miles away, and park, out in the country somewhere. Put one of those antennas to test on your vehicle, and transmit for a minute or so, and have your friend write down the S meter readings on his radio, deadkey, swing, etc. Rotate your vehicle 90 degrees, and do it again, until you've made a complete circle.

Replace with the other antenna, repeat.

Whichever gives the higher S meter readings would be the winner. But remember, it applies to your vehicle, but it may not apply to someone else's.

Just my two cents.

Jerry,

You're right, of course...

But I should point something out... 18' of coax won't hurt your radio, but neither will any other length. Whatever it takes to get from the radio to the antenna, then tune for best SWR.

Wha?

Are we exposing our theories already? The odds on door #1 are not the same as door #2 in the original example. In the second, the choice is 1/2 on both doors, but not because the car was not behind door #3!!! Also, are you saying the odds are the same for both Jim and his wife, after a choice has been made, as applied from EACH of their perspectives? This is also not true.

My explanations will be revealed when the call is made on the correct answer.......
Good one! - Damien

snip

You loose some and you gain some. In the end with the use of an
effective design you can come up with a net gain.

Let's make sure we are on the same page. Do you dispute this? Some
physically shortened 1/4 wave antennas CAN outperform the most readily
available full length antenna, the 1/4 wave SS whip.

If you dispute the last statement then make your own legitimate
comparison with an appropriate contender and prove it to be wrong.
No one has been able to do it yet. You could be the first.

Jay:

::grin:: Glad you have a sense of humor.

As per my opinion, based on my reading, the Wilson is not shunt fed.

Shunt fed refers to feeding a non-loaded (read straight) antenna from a point not at its end. I had alwayas thought of the Wilson as gamma matched, but that's also incorrect, as someone pointed out, due to the lack of a matching cap, etc.

Shunt fed antennas do not run the "short" end of the antenna to ground. The Wilson does. So I'm not sure what to call it, but it's not shunt fed.

Just my two cents.

I took a radio to the "tech" at the old Inglewood Electronics in California and took a loss too. The tech and the shop owner had a falling out and each denied having the radio! What kind of shit is that? I think their names were Dick and Tom. The shop owner died and the tech moved to another shop in Torrance. I was much younger at the time and had a lot of energy and brains. I'm glad I didn't react to my first thought. My second thought was to make sure this didn't happen to me again. I began to read and teach myself electronics. Although I'm no expert, I've learned a few things along the way. The main thing I've learned is people aren't perfect, OK, they tend to be fuck-ups! Do all you can to get your money back but above all, be prepared to take the loss. It's much healthier.

Miles Davis
This is CB radio.....No crying allowed!

hmm, I've seen that before.
your getting RF into the mic circuit somewhere.
did you open the case and do anything inside the radio?

did you move the station at all (or disconnect a ground lead somewhere)?

Does it do this on a dummy load (if not, you got an RF problem)

It does it on the dummy load. I've been inside it. Un-fsck'ed someone's bad peak and tweak (really a clip and snip), replaced TR24 (it had been cut), removed R131, opened the clarifier, mod'ed the PLL, and did the basic transmit tune up (adjust the synth, aligned the freq's, set the modulation, and adjusted for best power and sound). I've just never seen a 2000/148/GrantXL do this before. It happened after I adjusted the freq counter so it would be closer to correct (it was 400 cycles off). I didn't touch anything else....

I guess I'll start digging for loose ground wires and insulators.

Any other pointers?

Dave,

Have you looked at any of the "Carrier Suppression" type circuits that go between the Carrier Amp and the collector for the driver in single-output, AM only rigs? There are 2 designs; one using dual voltage regulators and the other based around a TIP120 or equivalent. Both allow variable power and modulated output to Max tuned power from what ever point the carrier is set to. The modulation limiter circuit remains intact.....

Output is relatively clean and audio level is maintained well above level of carrier. It is possible to turn power down to zero "dead key" and have "swing" to 10 watts (or what ever output will tune to on the meter you use to setup); however a carrier of at least 2 watts is needed to keep the signal from appearing to be SSB.

It is an AM only mod, and it will lessen some of the problems associated with trying to get high level audio from a modulation transformer based chassis.....

I've put the TIP120 mod in a couple of Cobra 29's... Get alot of good comments,
but I've never had one on a spectrum analyzer to see what it does to the radio's
output.. Any ideas what the output will look like?

I have purchased from Greg and had many email exchanges with him. He is very knowledgeable on the Browning gear and I feel he would be a very good choice to ship for repair.

JJ475171 <jj475171@aol.com> wrote in message news:20000820220150.11600.00000620@ng-fy1.aol.com...

No idea on the actual spectral purity. Audio reports are always good, and the overall performance makes the radio take on another personality completely. The TIP120 route can Make a Cherokee CBS-500 sound like a real radio.......

Since it is on the output side of the modulation transformer, and the limiter circuitry is still intact, it is being fed a clean audio signal. in relationship to the carrier level, the audio would probably be seen as over 100%.

Regency and Olson both used a Double Sideband suppressed carrier approach to AM in years gone by, and the results are in the same category; very little dead key and modulated output power comparable to other radios. The yield is higher level audio.....

Source record: 49169

Looking at upgrading my Uniden PC122XL, and am currently looking at the Eagle Sidewinder 400 (due to cost reasons). Apparently the channel mod is very easy (moving a jumper). Does anybody have any experience with these radios ? Are they more sensitive or selective than a "regular" CB ? Also, are they configured to fixed channels, or is their tx frequency variable ?

Thanks,

Richard.

Yep, I sure have... it's ME that all of the fuss is about. It has nothing to do with egos or exposure to high power RF. It's about a plain ol' ripoff... gear being misrepresented, and the seller not standing behind it. It sure has escalated into a real rat's nest, with some of the other participants using some bad language and racial slurs. I've tried hard to keep my posts clean, and stick strictly with the facts (and I have all of the facts, because I saved the original "for sale" post and all of the emails that we swapped before, during, and after the sale!).

I seem to recall a simular problem on a 148,a few years ago.It turned
out to be the MB37** regulator IC on the right side of the radio
against the heat sink.It seemed that it would go into oscillation.This
chip was also responsible for switching the different voltages on and
off for trans/rec and possibly am/ssb.One of the voltages were not
switching off all the way.It might be a good place to look.
Good luck

2659. polamar225 back swing HELP!

Newsgroup: rec.radio.cb
Date: 2000-08-21 00:00:00 UTC
From: crazyfool@theramp.net
Message-ID: <crazyfool-ya023080002108001011290001@news.flashcom.com>
Source record: 49182

Well I put the amp in the truck with my stock 148f and my k-40. I get forward swing in lo (dead key 30w peak 40w) but in mid it dead keys 100 and back swing to 75 and in high it dead keys to 150 and back swings to 100w.(BTW on SSB the back swing does not seem as bad)

What causes the back swing and how can I change it. I have tried these things to trace the problem:

1)Used my Bird dummy load to see if it was the k-40
2)Switched radios-cobra 19 classic
3)Lowered the output on the 148 to 2-3watts on the 148F.

Still back swings. Anyone have any ideas? Tools at work to my disposal: an ossiliscope, spectrum analyzer and RS power/SWR meter.(also have a Bird 43 but only have the plugs for 2meter right now)

I do own a Wilson 1000 for those of you who posted-lose the k-40, but its the roof top mount and I can't drill through the roof because of a large sunroof.

*Thanks to those who posted earlier about the install. I did use 10gauge strait to the battery.

Thanks for any input on my back swing problem...I sound like the air's getting suck out of my radio....

I believe that you may have this the wrong way round.

One way to tell if it is the fuel pump or not, is to rev the engine. If the noise stays at a constant level or pitch without rising and falling in relation to engine rpm, then it is probably the fuel pump. It could also be an electric radiator cooling fan.

Richard.

Actually, he never received it so he did not "possess" it. Whether he should have the right to possess it is another matter.

Being as there are many variables to consider, your question could only really be answered by testing and comparing each type on your vehicle, as one antenna may perform better on one vehicle than another and vice versa. Mounting location plays a big part. Also, how much "better" one is than another may not be easily noticed in day to day use. From what I gather, the 102" whips are supposed to be the best performers, but for most people thay are impractical, especially if they are mounted on the roof of a truck !! (watch out for those low bridges !!) Mounting one on the truck bed only lowers the height of the antenna, but I believe that the truck cab will then block a portion of the forward signal. In that case, a base loaded (Wilson or K-40 style) antenna on the roof of the cab may perform better. Also, you would still be able to load up the truck without worrying about damaging the antenna mount.

As an example, I have a K-40 antenna (not the best I know) mounted on the trunk of my car. With my 100 watt amp, I have spoken from up here in Ontario Canada on SSB to Florida, Texas, California, Puerto Rico and yesterday I contacted Italy !! Locally, I can speak 30 to 40 miles or so on SSB with the amp turned off. Now if I had a different or more expensive antenna how much further I would get I am not sure, but I am happy with what I have for now.

Richard.

Graeme,

Where did you get the kit from, and what models does it cover ? My fuel pump
on my 98 Sable drives me crazy !! (so does the electric radiator fan).

Richard.

Can I ask you to educate an old guy?

What I think I am hearing here is a variation on a couple of really old ideas that are still in use in AM and shortwave transmitters. There is a cute one which allows a transmitter to add audio on positive peaks without allowing an attempt to go below zero on the negative peaks. This does not seem to be this one. In fact most shortwave stations purposely run less than 100% modulation for better intelligibility under fade conditions.

The other goes by a lot of names but the one I heard most was 'controlled carrier' sometimes referred to derisively as 'Mongolian Modulation'. When there was no or little audio present, the carrier was backed down to reduce the electric bill, save finals, or to allow these finals to be pushed harder when necessary. When audio appeared, the carrier was brought back up to be mixed with the audio and a normal AM output resulted. The level shifts were a bit disconcerting to someone used to regular Ancient Modulation but beyond that it was pretty generic AM. It was used in the few cases I heard it to get a bit more out of sweep tubes when the plate dissipation would not handle the power level with full carrier.

Nobody claimed it did much more than keep the heat level down. Is this what these kits do? If so, why?

What do you mean, Jay? They knew they were in the 10 meter band; it's no secret the 10 meter band begins at 28 MHz. Operating at 29 MHz was no accident.

I am surprised none have bothered to 'fix' the problem. It may be an AM calling frequency, but there is a solution. I know there are arrl 'gentlemens' type agreements, but I believe there is one mode of operation available to licensed amateurs that is legal ANYWHERE in the band that will chop apart SSB (and especially AM) signals. W2OY found that out back around 1964 when he tried to clobber my poor 65 watts. You just change to CW. You get about 20 stations running CW over about 10 KHz of space and even the KW AMers are gonna get clobbered. Meanwhile, you can maintain an interference free 30 or 40 WPM cw contact in the same space. Of course, the FCC rules MAY have changed since I last operated HF (back in 1969), but as far as I know, you can run CW anywhere. Correct me if I am wrong. If I am correct, that is one way to take back 10 meters. No, you may NOT contact any bootleg station, but your station is protected whilst his signal is NOT protected. You are NOT jamming a legitimate station. Yes, of course you can buy morse code programs - but they usually don't copy well unless the code is machine sent - so, even if you have a good fist, change speeds a bit, hey, if you know it you can always switch to American Land Line Morse (I pulled that one on the guys on Guam who monitored all the communications out of KG6AAY - I'll bet they sweated for a week over the tape they had of our half hour QSO).

That said, please remember most CBers are very nice folks (as are most hams). It is just the few that get everyone riled up. So don't blame the decent folks, just exercise your right to 'share' the frequency - with about a dozen CW stations.

73s,
Jim

>very rarely will you hear american cb'ers on a ham freqs.

Sorry, Tim, I hafta disagree with you on this one. I live right along IH-35E in North Texas. The truckers are ALL OVER the lower end of the 10m ham band, using a-m. For a while here, there was a trucking company - rock haulers - whose trucks were ALL using 28.025 MHz as their "keep in touch" frequency.

It's true that the majority of the bootleggers on 10m are speaking Spanish, but an awful lot of them are located in the USA, talking "back home" to their native lands south of the border.

Someone else pointed out that these people are "bootleggers" and not "CBers". For what it's worth, I must agree. A "CBer" is one who operates a legal, type-accepted CB radio on authorized CB channels at authorized power levels. Anyone who does not operate FULLY within the law is a "bootlegger", whether it's done on a CB channel or not.

On a recent trip to Mexico, I was told that CB is illegal there, no matter what. That doesn't stop countless Mexicans from using CB gear, including taxicab companies, trucking companies, etc. If I was told wrong, please correct me.

Oh, and to head off the "ham-bashing" before it starts... the same reasoning goes for hams too!

Hello W7WJM: How do you know they were there on purpose. Did you hear the goins on? I have noticed that the ham radio fraternity needs to be reminded that ya get more flies with honey than vinegar ......ah lot.

I have asked a few of the locals not go past 28.0 MHz. and told them the old fart hams would have an attach, and choke. They got a big laugh and moved on.

How how ya going to stop the horde of illegal operators south of the boarder? I hear em from 12 meters into the LO VHF Band.

Rockin & ah Rollin in the Great Mojave Desert, ...just down the road ah ways from the fillin station.

Welfare Claire says: "I am ah lookin fer a man again, since Big Bob is on death row again. Tuesdays I am free"

From: Bill Eitner <kd6tas@netzero.net>
Message-ID: <39A17D46.8C97429F@netzero.net>
Source record: 49225

The Radio-Shack meter is notoriously inaccurate.

Also, with a 148 as a driver, the 225 will do about 180 peak
watts. If the dead-key is set to more than 1/4 of the peak
(45 watts in this case) you'll see backswing on an accurate
meter. The Bird is not perfectly accurate either. They
show the normal 4:1 ratio as 3:1. So, if the peak is 180,
you won't get backswing on a Bird until about 60 average watts.

The meter and your expectations are the biggest problems right
now. The 225 is really only a 40-50 watt amp when using average
reading wattmeters. The 225 face value is an overly generous
peak wattage that can't be obtained under normal drive and DC
supply voltage conditions.

You already set VR10 for a dead-key of 2 to 3 watts. Here's
the other little trick that will help: Solder the anode of
a 1N4001 diode to the emitter of TR41. Solder the other (banded)
end to the junction of R194, D63, and R228. (I can send a picture
if you send me a valid e-mail address that will accept a 73K
jpeg.) That will give you more average power with modulation.
Make sure TR24 is gone, and set VR10 for no more than a 2 watt
dead-key. Do all your measurements with the dummy load.

For an explanation of power measurements, different meters, and
the relationships in an AM signal, see the AM Tutorial on my website.
There's a link to it below.

Source record: 49228

The Eagle Sidewinder 400 is a great radio for its low cost. They have a really loud and clean modulation. The modification involving the moving of a jumper to effect the export channel completion is no longer accurate, due to a circuit change to the radio. The new channel modification involves soldering...but it is very easy to do.

DO NOT buy the Eagle Sidewinder modification video tape from Copper's or H & Y Electronics! They are selling an outdated video that was never updated with the new channel modification procedure. They changed the picture on the video box to that of the new radio, which has no markings on the upper center button, but left the information on the video tape unchanged regarding the channel mod so it is no longer valid.

The radio itself is very good though for the money in my opinion.

I accidently hooked up a CB on reverse polarity. I know i fried something in the back of the set just by that smell....

Question to those in the know: What is likely fried in the radio and is it worth fixing? Also, power supply doesn't work ever since this happened. What could have happend in the power supply?

Any help appreciated.

Vince

Depends on the radio. Most of the better sets have what's referred to as a "protection" diode. If you hook it up backwards, it'll pop, causing the fuse to blow.

You may have also blown a capacitor in the power supply, which would also make a funky smell. I Did the same thing about 6 or 7 years ago, blew a cap and the protect diode in one of my 148's... Took it to a tech, and $27 later I had a working CB again. Still have it, and it still works.

You can tell a blown electrolytic (The can type caps with the silver tops) cap by the smell, and usually you can see a brownish sticky liquid either on top of or on the bottom of the cap, or on the board surrounding it. replace that cap with one of the same values (same mF and voltage). If you tell us what kind of radio it is, I'm sure one of the techs here in this NG can tell you which diode to check for continuity and replace if its bad.

Hope this helps.

>prize. One of the doors hides a BRAND NEW CAR, and the other two each
>hide a BRAND NEW GOAT. You choose door number 1.
>
>Monty then opens door number 3, revealing a charming young goat. He
>says to you, "Do you want to stick with your original choice, or would
>you like to change to door number 2?"
>
>What should you do?

I have two solutions depending upon if you focus on the car or not (most
people do). Here are my guesses:

Solution # 1
~~~~~~~~~
Initially, you have a 1 in 3 chance of winning the car.

After door # 3 has been eliminated by Monty, you now have a choice of 2
probable locations for the car. From the above description, neither one is
shown to be more probably than the other.

Therefore:

>What are the odds of winning by staying with door # one?

50/50

>What are the odds of winning by changing to door # two?

50/50

Solution # 2
~~~~~~~~~
However, readind the question thoroughly, the question does not ask what are
the chances of winning the car. Therefore, if you look at the overall
picture, the chances of winning are certain or 100%, as a goat is still
considered a winning prize (by some people anyway).

However, having never seen "Let's make a deal" I am not sure if there are
some other rules that should be applied (I am a UK import).

Check near the back of unit where the power comes in there is a protection
diode, it is likly to be the smoked one, but they are black with a silver
band on them, this is the likely culprit replace this and you should be
back in business...

One last stab at this. Initially, your odds are 1 in 3 of choosing the
correct door. We know, with 100% certainty, that whatever door you
choose, there will be at LEAST one remaining loosing door. We will,
with 100% certainty, be shown the contents of A loosing door. We
cannot choose BOTH loosing doors. So the odds of choosing a wrong door
are two out of three. After selecting a door (with a 2/3 probability
of choosing a wrong door), we are shown the contents of a wrong door.
This now changes the probability (if given the chance to reselect from
the remaining doors) to 1/2 (of arriving at the correct door - but the
original odds still apply to either).

Read this and read this carefully. Once the third door is opened it is no longer part of the odds. The host asked if he wanted to stay with his first choice or choose the only door remaining. Only if you were stupid enough to pick the opened door would it take any effect on the 50/50 chance of winning.

It is like flipping a quarter. Two sides but only one has a head on it. You don't factor in the head on the dime in your pocket do you?

Some know and some don't. They purchase these imported radios with all the extra channels and they believe that they are cb channels. Some will gladly move if you explain it to them and some take the typical jerk attitude of, "I paid for this hear radio and I will operate any where I want to", or "If it aint a cb channel then why is it in my radio?", or "I don't need no stinkn' license to talk on this channel."

One problem I see. The FCC seems to be warning first time offenders, especially those who may not know better. The reality is that amateur operators may NOT contact stations other than amateur radio operators. This would preclude legally calling the stations and politely informing them of the 'problem'. I guarantee that amateur stations are more likely to get a harsher response than an unlicensed operator - partially because the unlicensed operator may be in another country, but mostly because the amateur is SUPPOSED to know the rules. The reality is this - I have had a lot of fun both using CB radio (oh the bunny hunts we had in the '60s) and amateur radio. Both amateur and CB services have their fair share of dunderheads who believe it is their right to use the airways in any way they see fit. It is those folks who cause problems between users of both services. I would hope most of us wouldn't judge the other group based on the actions of a few. My serious question as to the 'misappropriation' of 10 meters is why don't the guys start setting up some serious CW nets on 10? If you thing SSB can get through better than AM, just wait until you see what a dozen CW signals can do to just about anything (including much higher power stations!)

> Many hams (who are licensed to operate there) could not be copied through the
> bootleggers chatter. >>

1. These stations spoke english. Southern-accented english.
2. They either could not hear or were unwilling to hear friendly requests to move off.
3. "Cranking up the power" or jamming them may be the custom on CB, but most Hams would prefer not to do this.
4. The fact that the bootleggers might not have known what frequency they were on is no excuse.
5. If export radios were not so easily available in the US, the problem would be greatly reduced.
6. No amount of aw-shucks folksiness will convince10 meter bootleggers to cease.
7. Expressing an opinion about illegal operation is not "trolling".

>hide a BRAND NEW GOAT. You choose door number 1.
>
>Monty then opens door number 3, revealing a charming young goat. He
>says to you, "Do you want to stick with your original choice, or would
>you like to change to door number 2?"

I think it's time for the answer. Some have correctly answered
the puzzle. Most have not.

>What should you do?
Switch
>What are the odds of winning by staying with door # one?
1 in 3
>What are the odds of winning by changing to door # two?
2 in 3

The explanation:

If we just randomly choose a door we have a 1 in 3 chance of
getting the car. This also means we have a 2 in 3 chance of
getting a goat. Since the goat is the more likely choice let's
continue examining the doors with this 2 in 3 odds.

After our 2 out of 3 odds gave us the goat on our initial pick
we can also say that of the remaining doors there is another
goat and a car. Remember that this occurrence (one goat &
one car) happens 2 out of 3 times also.

Sticking with the game, out of theses two remaining doors Monty
will show us a goat. If these two remaining doors consist of one goat
and one car then the answer is simple. Take the last remaining door.
It has to contain a car 2 out of 3 times.

In reference to #5...

If matches weren't so easily available in the US, arson would be
greatly reduced, as well. ::snicker::

Don't get me wrong, I agree people shouldn't operate where they're not
licensed... Some are ignorant of the fact that what they bought is not
really a CB. They think a radio is a radio, and whatever the radio
will do, they'll do it.

Trying to educate the ignorant can sometimes be a futile task. Of
course, if they're ignorant, and choose not to learn, that pushes them
past the ignorance line into the "stupid" area.

Just my two cents.

Richard this is one of those trick questions that comes up from time to time. Last time I saw it, it was published in a national sunday paper magazine insert in the US called "Parade Magazine".

Like I said before, you should always change your pick when given the chance. 2 out of 3 times it will be correct to change to win the car. You can run a simple simulation to demonstrate this.

Draw three doors on a sheet of paper. Put a "G" for goat in the first two of them, and "C" for car in the last. You pick door one, Monty shows you door two with a goat, you win if you change your pick.

Draw three doors again putting the car in door two and the goats in the other two. You pick door one, and Monty shows a goat in door three. You win if change your guess to door three.

Again draw three doors, putting the car in door one, and goats in the other two. Monty shows you a goat from either door two or three (it doesnt matter which) and again you change your guess to the door not shown. You lose. Two out of three times you win if you change your pick.

You can play with this simualtion where your pick is door two or three, and you will find that changing your pick after Monty shows you a door with a goat in it always makes you a winner two out of three times.

Remember, at the start, the chances that you picked the correct door is one in three, making it the odds that one of the other two doors holding the car two out of three. After Monty shows you a door with a goat in it, the odds that your original pick being correct is still one in three. And the odds of one of the other two doors holding the car is still two out of three, except we know which one of them holds a goat, which makes the remaining door a two out of three favorite.

Well, actually, flipping a US coin does not produce an actual 50/50 ratio. Due to the striking characteristics, the center of the coin's weight is offset somewhat toward the 'tail' side, hence the odds are slightly improved toward the coin coming up 'heads' when tossed randomly. Just another trivial stat fact from a guy who has more college hours of statistics than he would like to admit to.

As others have said, it is likely a diode. If you're handy enough with a soldering iron to replace it yourself, your repair may cost you a dollar or so. I'd saya yes, it's worth fixing.

not a terrible rig, good audio, etc., and lotsa channels, but a few flaws such as losing the memory of what band you are on when powered down, and overall workmanship isn't up to say a 2510 level. They are around used if you look, but in all honesty I would put away an extra 50 bucks and look for a good used 2510 or 2950, worth waiting for a couple of paychecks...

I have never purchased anything from this nut, so i can't comment on Jack-The-Wackoff-Thurston-Howell-The-Fifth's business practices.

But i had a couple of long distance heated arguments on 38 lsb with this stuffed shirt retard. This dink has the fart-filled-balloon that is his life revolving around his yawned-out religion that it's his mission to police the radiowaves and harass anyone he see's fit too.

Which of course is practically everyone...i.e. anyone with a power mic or loud modulation, echo on their station, or any operators who don't talk like a robot with run-down batteries, etc.

Oh yea, i almost forgot, he hates anyone from California. I have heard him call at least 10 people from California faggots. He will even listen to long distance skip transmissions and when he hears a QTH exchange, and one of the stations is from California, he will start harassing the non-california station calling them California faggot-wanna-bee's and so on.

Like most Californian's, I am not a queer, and i do not associate with those types of people...and when i pointed this out to ol Jacko, among other things, and he realised he had lost the argument, he did what every
never-should-have-been-born-can't-tell-his-ass-from-a-hole-in-the-head-sub-standard-deluded-moron
does....he started doing the equivalent of keying up on AM on SSB by making stupid sounds so his Arizona bone-smoking radio buddies could not hear me shred his ding-a-ling universe any more.

I think he was having sex with the Yak he uses to plow his 40 acres in Sin-Valley.

Now deny it you black hearted freak-of-a-bitch, and i will put up a website which will have tape recorded sound-bytes of you harassing people on SSB.

Trust me on this, you do not want to do business with a person who is this black hearted and mean spirited.

I would not put anything past this shit-for-brains-maniac...it's obvious to me he was poop-shooted into this world.

I don't know Jack? Sure i do, just like the original poster who has a serious complaint against you, thats why our reality of you as it trully exists allows us to concretely know that, with out doubt, you are shit.

Learn the law and decide for yourself if freebanding is for you. There are many freebanders above and below the conventional cb band and these channels offer DX that rivals those of HF rigs when conditions are running, but along with this great area for DX comes a chance of being popped. Learn the consequences and decide for yourself if it is somethng you wish to do, but make the decision on your own. If someone can't point you to a frequency chart on the web, I'll send you one.

I prefer the word "freebander" to bootlegger. Maybe bootbander would be more accurate. Never could figure out why some freebanders would talk on the 10 meter band when there is so much great space in BETWEEN the bands.

Tim,

In the end, that is the most consider definition and explanation......

If they used a woodpecker to tune with, the channel would be available a lot more to folks that talked more than they tuned. Sometimes the ones that go "audioooooooooooo" all day long are already talking to the only one that will have a conversation with them..... themselves.....

Because stainless set screws can be problematic. They are not nearly
as reusable as a standard set screw. The hex rounds out rather easily.

Of coarse standards have problems with corrosion. but this can be
corrected by the proper use of products like Noalox.

You play the odds.@ out of three times you WILL pick a goat.

>> Sticking with the game, out of theses two remaining doors Monty
>> will show us a goat. If these two remaining doors consist of one goat
>> and one car then the answer is simple. Take the last remaining door.
>> It has to contain a car 2 out of 3 times.

>who said the last two doors (meaning the two you didn't pick) are not goats?

It can be. But only 1 out of 3 times.

Again if you determine the major odd as 2 out of 3 in initially
picking a goat then you will have one goat and one car remaining. This
WILL
occur 2 out of 3 times.

2772. Re: Has anybody installed a channel-guard?

Newsgroup: rec.radio.cb

From: Mike Frye <km6ab@pacbell.net>
Message-ID: <39A1E276.DC1E7B58@pacbell.net>
Source record: 49295

A long time ago (20yrs?) a Royce CB came out with a novel idea of cascading two 455kHz ceramic filters instead of the usual single filter. We found that on many radios adding a second filter was very easy, improving the adjacent channel rejection and only slightly affecting the overall sensitivity of the receiver due to the insertion loss of the second filter. All you needed was a little room on the circuit board close the original filter and you could drill the necessary holes to mount the new filter and then cut the trace from the original filter and connect the second filter with very short wires. Many SSB radios with larger 1st IF filters like your 10.695mHz have the 455kHz filter in circuit even in the SSB mode and should benefit from the extra filtering. The 455kHz filters for most radios are sold by DigiKey for about $5.00. I suspect this is what the "channel guard" is that your talking about. Channel Guard is also a registered trademark for GE and Ericson tone squelch in FM radios......

I was just wondering what the difference was between their 35amp supply and the "Gold series"? Just somthing I am curious about, and are the Gold series still made, I don't see them in catalogs, just on used equipment shelves.

Around here, we don't put up with illegal operators and "kerchunkers".
Some of the local "extras" get out the RF direction equiptment, and
that's the end of that.

Why can't all you idiots just operate legally? If you can't do what you want to on CB, get a ham license. (not that ham is better then CB or anything, each is something completely different)

That is if you have a radio on your possesion or they have went to your house on a complaint. You can buy the amp for parts and take it apart there is nothing illegal about that he may buy it and sell it to a ham who is going to use it or modify it .There is nothing that says you cannot purchaes or own the amp as a US citizen. If you have radio equipement they will assume you have used it . So your saying that any amp must be treated like a plague and not be sold or touched or found in your possesion otherwise you will be in /fined jail. Tell that to all the surplus electronics buyers who have these things laying around to sell for scrap and parts

Well then looks like there should be a price war because Exportsrus prices are very high on all amps. why would someone pay the price you are charging when they can get the same style amp delivering the same watts for much less money. and from the guy whos design they are based on It just doesnt make sense. I have seen enough of each amp pass thru my shop to know they are built the same and do the same power.

My my, you can always tell when someone knows they are losing the argument, they resort to using vulgarities. There are some cb operators who have been fined for simply possessing an illegal amp that would disagree with you.

Hi

Now that I have your attention . I`ve been out of the CB scene for a little while and am looking to put one in my Jeep once it`s road worthy . Now I used to be a "pro" at tricking these radios out and what I want to know is , do the new Cobra 148`s still have the same good old modifiable chip for getting "better" freq coverage ? I have seen some good deals on new ones that have that night illumination feature. Just upgrading my info. Thanks !!

Jeff

1. Only in America...can a pizza get to your house faster than an ambulance.

2. Only in America...are there handicap-parking places in front of a skating rink.

3. Only in America...do drugstores make a sick person walk all the way to the back of the store to get their prescriptions while healthy people can buy cigarettes at the front.

4. Only in America...do people order double cheeseburgers, large fries, & a diet coke.

5. Only in America...do banks leave both doors open & then chain the pens to the counters.

6. Only in America...do we leave cars worth thousands of dollars in the driveway & put our useless junk in the garage.

7. Only in America...do we use answering machines to screen calls and then have call waiting so we won't miss a call from someone we didn't want to talk to in the first place.

8. Only in America...do we buy hot dogs in packages of 10 & buns in packages of 8.

9. Only in America...do we use the word 'politics' to describe the process so well: 'Poli' in Latin meaning 'many' and 'tics' meaning 'bloodsucking creatures'.

10. Only in America...do they have drive-up ATM machines with Braille lettering.

11. Only in America...can a homeless combat veteran live in a cardboard box & a draft-dodger live in the White House.

COLD as ICE and TWICE as NICE.. Mr. ICECOLD BIG APPLE TREES says.. It don't mean a THING if you ain't got that SWING!!!!!!!

Hi Chas, #12 doesn't play here anymore. Some @$$O sent a letter to his employer pointing out his participation regarding various radio related upgrades and caused him a lot of grief. A loss to everyone in this NG. I will pass your hand next time I see Sean he talks to Dennis on a regular basis.

Hello all, Over the last few months ive been in close contact with a fellow who I beleive to be THE BEST, and FASTEST repair person, ive ever had the pleasure of knowing..........(thank god) If you've ever had to do any kind of business with "Phil Nichols" AKA, (former Browning Engineer) you MUST know, that hes as slow as SH_T. and NUMEROUS others out there are just, "wannabee" techs, when you get something back from one of these "wannabee" guys.............YOU WANNABEE ABLE TO PUT A FOOT UP HIS NARROW ASS for screwing the radio up more than it EVER was in the first place!!!!! Anyhow, the guys name is; Greg, he runs, Barkett Electronics, 372 John Johnson Road, Trinity Alabama, 35673, and his telephone number is; 1-256-350-3848, this guy is the best, he got me out of such a jam the other week, and from the moment I shipped the radio, to the second I got it back, it took only one....(1)....week. you wont find that kind of service ANYWHERE, even locally, these guys drag this shit out. so please guys, I know how much some of you treasure your "Prize" Brownings, and Trams,.........DONT SETTLE FOR JUST ANYONE, Greg, will go out of his way to accomodate your needs, and work with you, as much as he can, He really dont need me advertising for him but I told him that after what he did for me,from now on, I will be forwarding ALL of my business to HIM.........thanks all, and 73........
Frank in Connecticut.

> one, I don't know, and two I'll bet we'll be on it for days. =)

In a standard AM signal half of the power is in the carrier and the other half is divided between the two sidebands. The sidebands carry the intelligence. The carrier just goes along for the ride and contributes nothing to the intelligence. In SSB, the carrier is suppressed, one sideband is filtered out, so all the power is in the remaining sideband. So for a given power, SSB will win.

2808. No Wonder Why Hams Are Pissed

Newsgroup: rec.radio.cb
Date: 2000-08-21 02:18:33 UTC
From: x34956171135@aol.com
Message-ID: <20000820221833.16102.00000581@ng-cc1.aol.com>
Source record: 49138

The 10 meter phone band was open today. A group of unlicensed CBers (men and women) parked themselves on the AM calling frequency at 29.000, operating LSB. Many hams (who are licensed to operate there) could not be copied through the bootleggers chatter.

So don't be surprised when we bitch to eBay and ask them to pull your "export radio" auctions.

i think their radio regulations suck, and it is probably because the hambos started whining about the sale of what they construe as being illegal class c-fcc type-not-excepted amps, ebay is making a mint off of this thing i can assure you. i just wish i could get a date with the president. she is single and kind of cute. of course i am not sure if she would mind me keying up my radio from time to time squashing mudducks and hambos who try to interfere with necessary curious communications, can you dig it,.....cd is out.....

why go to all that trouble, unless of course you are dead certain you
want a cobra. heck get a galaxy or some other radio with the wide band
coverage already in it and freq counter to boot, of course you could
get a cobra 148 dx radio. same difference, cd is out.....

From: RICK <vk3ym@iprimus.com.au>
Message-ID: <39a240b0@news.iprimus.com.au>
Source record: 49306

Question... Who is the actual manufacturer of the 102" or 108" Stainless steel whip antennas..
Are they made by only one company or is there actually several who manufacture them..
Are they still being manufactured???

The reason I ask is that I am still using my original one purchased in 1976 and it has outperformed all other antennas I have tried over the years... Last weekend I transferred it to the 8th vehicle I have owned since getting it and it still performs as new...even the ball/spring mount is original..it cost me $49.95 total when new and was sold under the Hygain Brand name.

Rick
BTW... via an antenna tuner I also use it on all H.F. ham bands as well.

Dan:

Part of the problem is that, in order to get voice priveliges on HF as a HAM, you need to pass a code test... Many people, myself included, are dyslexic, and can't tell a dit from a dah. Now if I could find an Elmer to teach me the "trick" to code, I'd probably get it down pat, but so far as I know, there's not many HAMs in my area.

I like to talk DX on side band. Unfortunately, there's too many people out there who don't recognize the "gentleman's agreement" that used to be in effect concerning which channels are AM and which are for SSB. So you get the "freebanders" who will go above 27.405 to talk. I have done it, I'll admit, on more than one occasion. I have never talked above 28.000. Heck, I, have stayed between 26.810 and 27.800 my entire time on the radio.

I've never been asked to move by a HAM, but if I were, I would, no questions. I DO NOT want to interfere with anyone else's enjoyment of either hobby. I try to tune my radios so they are loud enough to do the job, yet not loud enough to splatter 48Kc each way, as some are wont to do.

We're not all idiots. Some of us just would like to get away from the Hash and Trash, the rude behaviour, and just talk. If only the FCC would open up some channels above 40 for side band use only, I'd be utterly thrilled. I don't see it happening any time soon, of course.

Just my two cents.

Don't whistle... Use one of those old casio synths that cost about $20
(you know.. the ones that double as a calculator) and play a middle C
into the mic.. you'll get a cleaner representation of what the radio
is doing modulationwise if the source being modulated is more
constant.

As for the rest of it, I don't know. Someone here will.

I believe that your answer is incorrect based on the way the puzzle was presented. The contestant chooses door number one, and Monty opens door number three, which reveals a goat. He does not simply open one of the other doors to reveal the goat but specifically opens door number three.

Before the contestant chooses a door, there are three possibilities -- the car is behind door number one, door number two or door number three. The contestant chooses door number one and has only a one in three chance of being correct. However, the possibility that the car is behind door number three is eliminated when Monty opens it to reveal a goat, so we know that the car is either behind door number one or door number two. Now the contestant has an equal chance of winning the car by switching or by staying.

If the puzzle had said that Monty opens one of the other doors to reveal the goat without specifying which one, then your answer would be correct and the contestant would win the car two out of three times by switching.

This was a fun distraction -- thanks for the mental workout!

Message-ID: <39A249B7.97B8307@island.net>
Source record: 49313

Ahhh, Chris but it will!

It will over modulate the radio causing high levels of harmonics, cause the radio to splatter over several channels up and down from the one he is on. And depending on the radio design cause other problems.

For example here is the procedure for doing a proper tune-up and alignment for a Galaxy...

Adjustments for:

DX 77HML, DX 88HL, and DX 99V

1.VR 1....AM/FM S-Meter
2.VR 2....SSB S-Meter
3.VR 3....SSB Squelch Range
4.VR 4....AM/FM Squelch Range
5.VR 5.....FM Deviation
6.VR 7....SSB Carrier Balance
7.VR 8....RF Meter
8.VR10...Final Bias
9.VR11...Driver Bias
10.VR12...SSB ALC
11.VR13...AM/FM High Power
12.VR14...AM Modulation
13.VR16...AM/FM Low Power
14.VR20...Final Bias
15.VR21...TX Offset
16.Unmarked VR in R189..AM/FM Medium Power for DX 77HML only

This requires a signal generator, oscilloscope, preferably a signal analyzer, and a certain procedure of progression as some settings effect

others.
Cheers,
John

Don't think the winding on the choke would be burned in two... That would be the only real failure mode for it. I have never seen this before. The choke is a very low DC impedance and would have to have perhaps 50Amps go through it to burn in two. Probably the source you were hooked to... didn't even have that current capability. And even if if did... the fuse on the set should have gone was before that point!

Replace the diode and give it a try...

Thanks Scott !!

It would appear that once you hit channel 26, the frequency becomes
27.(channel #)5. Past channel 45, do they continue in the same manner ?
(assuming all radios allocate their channels in the same manner).

Richard.

Maybe "CB channels" was the wrong phrase to use. But there are export radios
with "channels" that do go above the regular 40.

>each is something completely different)

Wow !! I didn't mean to start a debate/slanging match. I did not say I was "for" or "against" anything, my Uniden PC122XL only has 40 channels anyway. I just wanted to know what frequencies I could listen to with my shortwave receiver for now to decide whether it is worth getting a radio with more channels or not. From what I can gather from reading this NG, a good majority of people use opened up HAM rigs instead of "regular" CBs anyway (this is also true for probably the majority of the CBers up in my area).

Richard.

rhin022,
The simple answer is that you adjust the antenna's length
to tune it, or the matching network if it has one. You tell
when it's getting close to being 'right' by using one of
several kinds of meters. That's the 'quick and dirty' answer
to your question.
'Doc

First off, Friedrichs, the only idiots around here are the one's who feel the need to name call when something is said they may not agree with. What do you mean, can't do what you want on cb? I certainly never ascertained that. But now you come in preaching legalities about getting a license. Getting a license won't allow you to operate on the bands that he asked about. Besides, check out Hollingsworth's acivities. Each month it is a ham, not a cber getting popped. Wonder why that is? Could it be the hams are more problematic? I have not bothered to check the archives, but if you ever talked skip on a cb or had a modded radio, you, sir, are a hypocrite. The law is the law is the law is what appears to be the prevailing attitude among those who cry the loudest about freebanders. Whats good for the duck...'er...goose...Using your own logic, tell me why many hammies get their ticket and then mod their radios to go back to the 11 meter band where they started? Why don't they just get a cb? For crying out loud, if someone is on 555, why the hell should that bother you, other than you got a ticket and feel others should have to do the same. That mindset of "I got mine so you should have to also" wore thin many moons ago. I have alot of friends who have their ticket, but as long as noone bothers them, they can give a flying leap what someone else is doing. Worry about your own backyard, and the space between 11 and 10 meters is not yours to mow!

Having taught code etc quite a bit (back when 13 was the standard) I encountered similar problems with people whose jobs required performing similar operations in mirror image. Two classics were a house painter and a guy in charge of air brakes on Gussie Busch's railroad (still a good friend). Without having the slightest idea what it means to be dyslexic, my gut feel is that it is a matter of degree so maybe some of the same techniques will work.

Without beating it up here (feel free to Email) it comes down to two things:
1) you will have to learn the code at at least 16wpm. Don't freak on me; in some ways it is easier.
2) You will have to go to some lengths to convince yourself that code is a right-handed activity. This means putting the left hand in your pocket, directing the sound to the right ear, etc. The first few days will be a class A bitch but it can be done.

Before lighting up my Email box, get some good freeware, set it to 16wpm random groups, take off your left shoe, tie your left hand in your belt, assume a casual position (no need to associate code with galloping tension headaches) and simply make a mark (/is good) for every letter you hear until you get the rhythm. Then some quiet nite, make the marks but pick out A (di-dah) and enter it in instead of the /. Then email me.

Practice for no more than 30 min twice a day and never at anything less than 16. If you get gung-ho use the General and Extra study guides for bathroom reading.

You most certainly have my sympathy but it may well be a solvable problem.

Have one messenger M650FR amp;

1 driving 8 SD1446s, does about 700W PEP tops with good
alt or stiff supply. This unit is designed to be full remote, and as

such has a remote control head unit as part of its design. Class
AB1, clean as a whistle on SSB. Excellent condition, includes
ferrite on power leads and on remote head. Has 120MM ball bearing
fan mounted to heatsink. (externally powered..) keeps this bad boy
cold under duress.

Asking $500 or best offer.

-Mike

well hippie, if you have someone in the area that has bought a new texas star amp as of late, you can take the osc. that they remove from it in the conversion and add a 9 volt battery and a xtal......wallah! a signal generator.
they work great and they are "rock" solid. (no drifting)..... Got somebody ya don't like? crystal it for there home channel and drop it off in some bushes in thier yard. he he he..... sometimes I get evil thoughts.

Cales lengths can matter when there is a standing wave present. Even
a low value may make a difference back at the rig. Could possibly
affect the real output, especially if there is an automatic protection
limiter. Sometimes instead of worring about cable length, just use a torroid
with a few turns around it, near the rig. Somewhere between 25 to 50 feet,
I would consider going to larger coax to get less attenuation, but its not
that important.

there is several companys that make the steel whip, some are better than others... you don't want the ones that set screws at the bottem...it says they are for adjusting swr. Ha!, no adjustments needed if you have a solid mount and a good ground.... they are just a good way to loose the antenna. I guess so they can sell you another one. The only one I carry is the Hustler. I've yet to have my first problem with them....

2872. A Challenge For All The Resident Antenna "Experts?"

Newsgroup: rec.radio.cb
Date: 2000-08-22 00:00:00 UTC
From: AntennaWareHouse <kingpop@cis.net>
Message-ID: <39A2B1E8.B0540843@cis.net>
Source record: 49400

There seems to be a awful lot of you self taught Antenna Gurus that think that it is impossible for a Monkey Made Antenna or other similar type antenna with a coil incorporated in it's design to out perform a full size quarter wave whip. To separate the the parrots that have learned what they repeat from dubious source from those who have had the advantage of formal training in field of electromagnetic field propagation as well as a good part of a life time of work in the antenna manufacturing field, I would like to issue the following challenge. I bet $1000.00 that no one can can show up at the door of my business with a full sized quarter wave antenna that will out perform the shortened Monkey Made of my choice in range field strength measurements. It's time for you know it all's to put-up or or shut up.

This challenge is open to anyone that can call the bet. Except for that psycho babbling DaveDeb I don't want that kook anywhere close to the town I live in!

How about it Professor? You live fairly close to me. Got a $1000.00 you want to give up to back your mouth? I'll even give you the Monkey Made as a booby prize after I take your money.

I have the range and I have the measurement equipment. Bring it ON.

dude this has nothing to do with ham
we are still talking about cb antenna
you have guys that have lots of money and the buy what looks good and so on
and have no clue about your basic antenna
theory or pricinpal behind it and how to improve it perfect example how many
times have you travel and seen a man in a suite just looking at his flat tire
with the instruction manual and still can't change the flat istrue istrue well
it also applies here he can't change a flat but he can drive a car right well
there are lots of cbers that know how to talk on the radio but have i dea that
it is the antenna system that makes the big difference not so much the watts
you have to double your power to see a half of s unit difference where with
antenna do can get the same results or better is tru is true so don't start
that bull crap hamboo shit nothing but pure cbing here sandpile willy

Sideband: now that's something I agree with. Everything but the extra channels part. If you want to talk DX, stop whining and learn the code. It's not that hard. I've only been working on it for 4 days now, and already am up to 2 wpm. CB is not for DX, if you don't like it, too bad. You don't get to decide that.

I would take that bet if 1) I lived close enough & 2) The Monkey antennas you choose are 5ft or less in lenght & mounted on the same spot on the same vehicle.
I think when you get to between 6 & 9 foot with your "monkey", "Parakeet" or whatever, the length is too close & a 102" may not "outperform" at that point, just proving you need to be at or very close to 102" to work as good or better than a generic less expensive 102.

Daniel I would say it is damn near impossible. Just think about it. You hear a trucker on 28.500 talking to his buddy. You jump in your car with your 4 directional antennas on the roof (as an example). You drive towards the direction the signal is coming from. What about the skip? The operator could be in New York state and your in Vermont.
I not an expert on this but I wish you would outline to me how you would track down a trucker. Sometimes I hear guys in South America and they sound like they live next door to me. (I live in Canada).

If you did by some chance track down this trucker what are you going to do?

It continues past 45 in the same manner. If your radio has bands and is not continuous like a 2950, you will skip channels and flip around between 22 and 26 like you see on the chart. You won't hit channel 44, 49, 54, 59 and 64 without a 10 KC switch because the channel selector is designed for CB and does the same tricks on other bands.

You must not have been following the former thread that resulted in this challenge. The antennas that were referenced in that thread as having a slight but measurable improvement were in the 7-8' range with a elevated coil.

Dick:

Ok.. I'll give that a shot. I have Morse Tutor Gold (Or something like that), and it hasn't done me much good, but then again, I never did it at 16 WPM either... I'll give it a shot.

Basically I can't tell an A (dit-dah) (to use your example) from whatever letter a Dah-Dit is. For me, it only seems to affect things I hear. I read and write just fine (I don't use a spell checker, if that's any indication), but I still sometimes get my right and left hands mixed up. I'm an odd case. I play guitar (or at least I try to), and sometimes I get a couple chords backwards, etc. You get the gist.

At any rate, I hope you understand my point about the freebanders. It's simply a desire to get away from the regular "hash and trash" and do some serious long distance talking without having to deal with carriers, and other such interference.

At any rate, thanks for the ideas about the code... I'll try it and see what happens.

are you a haole, braddah? hawaiian definition of haole= foreigner. english version of foreigner = one who is from a foreign country or place/located away from one's native country. meaning if you are not born/raised in hawaii or no hawaiian ancestry, you are not hawaiian. as we say here in hawaii you can be hawaiian at heart (aloha spirit) which foreigners do not have and probably don't understand. and yes i look damn good in a hula skirt.

i'm not picking on you or trying to make a mess here. just wanted to clarify things when you asked about hawaiians being crooks. you probably would have offended many hawaiians which they are proud to be. just like americans are also proud to be. i am proud to be an american citizen just like everybody else, thank you.

2897. Noise, 77-103, Pathfinder

Newsgroup: rec.radio.cb
Date: 2000-08-22 00:00:00 UTC
From: ryanp@ctron.com
Message-ID: <8nuoq1cfa1@nnrp1.deja.com>
Source record: 49425

I have a Midland 77-103 which I have connected in my 97 Nissan Pathfinder. I'm using a lighter adapter cable connected to the rear cigrette lighter socket. this is the socket nissan says you should use.

With the engine turned on I get a pretty loud whineing type noise on the CB radio. this makes it nearly impossible to hear most transmissions. the tone of the noise does not change with engine rpm, but changes very slightly with battery drain, like headlights etc.

I tried the radio on my friends Jeep crand cherokee and there is absoutly no noise except for the usual static.

how do I eliminate this noise.

Thanks
Ryan

I just looked at your web page you really are a jerk-off If you are the next great antenna guru why are you selling everyone elses antennas ? Why don't you sell your own brand something that you have designed on the "range" with your BSEE from Iowa. Does that BSEE stand for bull shit extrodinare ehh? When was the last time anyone used antenna to talk on a antenna range. Why not try a test out in the field. A 30 mile test across town a 10 mile test etc... Go peddle your bullshit to someone else... Maybe the ham NG will buy into it.. I got a $2000 dollar challenge directly to you to come to my location and bring any antenna you like ... Come get that Monkey off your back..

What's the big deal about proving that an expensive center loaded 8ft antenna may perform slightly better than an unloaded $20 9ft??? The general "rule" has always been , given the same general size antenna, the higher up the load, the more effiecent.....A properly tuned 4ft centerload should do better than a 4 or 5 ft base load etc... A "top load" stick would be better than locating the load in the center or bottom of a similar antenna.
I'm more interested & wonder if the Monkeyman antenna would actually do better than a fraction of an s unit on an actual CB in comparison to a 1/4 wave in the same mounting location. Someone could prove, for example, that 22 watts is more "power" on various watt & other meters than 20W, but we know that you "really" need 80W to bump up 1 true s unit (6dB) , so big deal if a radio that costs 75% more than mine has "22W" instead of 20.....

2909. Pro520 question??

These are very good quality... but when using a whip like this be prepared
to be directional if you don't mount this in the center of the roof of the
vehicle. That is one major advantage to coil-loaded antennas... being able
to do this.

East coast to west coast will be at least 2 bounces. It's too far
for a single hop. A single hop can cover 300 to 3000 Km on 11 meters.
(or is that miles?) Baltimore to MO is where we get it from about 10
to 11 PM. The next hop west is over water.

The Parent company of www.antennawarehouse.com, "Monolithic Electronics Inc." Does have a another company under it's umbrella that does sell many antennas of original design to governmental and commercial interest. I didn't know you were in the market for a radar array. I would send you a brochure but I don't believe you can afford one. My son is the real management behind the antennawarehouse website. He sells good Antenna products at some of the best prices around. Personally I think he is doing a great job. You Dad should be so lucky to have a son he can be proud of.

Going by my knowledge the best commonly available mass production
full size (no coil) 1/4 wave antenna would be the 8 foot Francis.

I don't know of any other full size antenna that will beat the
francis.

Of coarse I do have direct knowledge of some commonly available mass
production * Ugly 1/4 wave loaded antennas that will beat the full
size commonly available mass production models.

Conclusion: I'm not going to take your bet. I know better.

* Ugly Antenna = An efficient and fairly tall antenna that is
constructed of highly conductive materials and contains an upwardly
located coil that is large in diameter and spacing.

I picked up a Pyramid PK-52 rack type 52 amp power supply at pawn shop today
$ 100.00 I guess thats a fair price?
Question is it has adjustable voltage knob from 12v to 15v where should I
set it to run radio (grant lt) and any other lets say......accesories
(palomar 250) for testing purposes only of course?
13.8v? or will it hurt to go up to 15v ?
Thanks,
Ken

I don't give rat tits whether you freeband or not as long as it ain't where
I want to go. Judgment ain't my thing.

The idea, if you have not figured it out already, is to do it at a speed
that cannot get both sides of the brain involved at the same time and to
take some steps to designate what side it is going to be -- the one you
write with seems to be a good place to start.

Back in the 13 days a lot of people went thru a 'hump' at about 10 where
they started to experience 'inversions'. Sense inversions reversed dit and
dah so X became P and J became B. Also there were sequence inversions, the
familiar F and L problem. My feeling was that somewhere in the process, a
transfer was being made between two sides of the brain and getting screwed
up in the transition. Let it be said I have no training whatsoever in this
field.

Hope it works for you.

Dick

Twisted,

Waaaal, that isn't exactly true. I'm only going by your saying you had not checked the archives lately. He hit a guy in Fla last month for unlicensed operation (not a ham), and another one in California. He hit a glider club in Cali for using 2 meters recently, and a cab company in Alaska for unlicensed ops. While I agree that the majority he's gone after are hams, the others DO get attention. No judgment meant, but with the improvements in their monitoring equipment, it's going to likely get worse for all illegal operators. The "freeband" will most likely be the next target. For the stateside people who use export rigs and intentionally or unintentionally encroach on 10 meters, they are getting attention now--like the "Rabbit Ears" guy. He didn't believe their NAL for $20,000, and kept on even after being cited. So he went to jail and now may face jail time and $10,000 for each offense. For my part, I don't care what the freebanders do, etc.--just as long as they don't bother me. And they AREN'T. So I'll just be a 40 channel mud duck and leave them alone. Just my 2 pennies.

Jerry
Besides, check out Hollingsworth's acivities. Each
> month it is a ham, not a cber getting popped. Wonder why that is?

Source record: 49475

Greg,

The reason that there IS SWR is because the antenna is not resonated, OR the feedpoint impedance is wrong. If you change the coax length and don't resonate the antenna (usually by lengthening the radiator/whip), and get "improvement" then you have "masked" the REAL trouble and fooled the radio into seeing a 50 ohm load. Remember, the radio doesn't care if the antenna is "efficient" or "resonant" IF it sees this nominal 50 ohms. That 50 ohms can be feed point, coil resistance, or radiation resistance--it usually is a combination of all three resistances. That's why you can use a dummy load. The radio will load into that resistor, BUT you still don't get any signal out (not a useable one, anyway). So by trying to get a "low" SWR thru cutting coax, you are treating a symp-tom, and not the cause of the high SWR. And that cause is usually a mismatched, or mis-tuned radiator (antenna).

Your right, I'm not familiar with the International Organization
for Standardization ISO-9001 (4.10 and 4.12) standards. Since I'm
not manufacturing anything, I don't have to be. I did ask a very
simple question about the testing procedure you planned to use in the
comparison test. I can only assume that by your reply you would
rather belittle, insult, and cloud the issue, since that's what you
did instead of answering the question.
Would you like to try that again? Try not to be so 'snotty' this
time, and please make it very simple, so a very simple person like me
can understand it. If you can't, ot won't, I can certainly understand
that too.

Source record: 49478

Barry,

Actually, it's not hard at all. The feds can sit in Maryland and track a vehicle with their current technology. As to skip, if you are tracking what appears to be a local signal, you attenuate the receiver's sensitivity. Even triangulation (the same technology used by some air navaids) can give a general area. By taking continuous readings, or sampling at regular intervals, one can tell if the target is moving or stationary. All it takes is a couple of stations with beams and a map. One takes a beam heading from his location, and the other guy does the same. The lines are run on the map to the edge. If the transmitting station is within the area covered by the map, the lines plotted by the two stations will cross each other at some point. This is the approximate location of the transmitter. By establishing these "fixes" at a regular interval, while one can't exactly pinpoint the radio's location, one CAN establish a direction of travel. Then the ground units can go in and DF the "offender". That is very old technology, has some limitations, but can be quite effective. Now, all they have to do is use satellites(of course, you've heard of GPS) to lock onto the signal, establish it's "footprint", and follow it to its destination. As a matter of fact, hams use this technology (it's called in that application APRS--Auto-Positioning Radio System) to talk with one another and pinpoint each other. And some trucking companies use versions of the OnStar system to know where their trucks are at all times. So it is VERY easy to pick out a mobile radio transmitter and follow it. Lastly, go to

www.rainreport.com

where you will see that FCC has nailed some truckers--some hams, some not--for malicious interference. Being mobile is NO guarantee of immunity. I'm not sure what system they used to do it---maybe somebody just "snitched". LOL!

Best 73

Jerry

P.S. I know you're in Canada, so when I speak of current US technology, I am including Canada also. I'm certain the technology is available all over the world.

Hillbilly from my home state!
If you are talking about the setscrew collets, there is a simple fix to prevent losing the whip. I simply cut a small notch in the whip with the "flat" side of the notch towards the bottom of the whip and tighten the set screw within the notch. A properly tightened setscrew will not allow the whip to get out of the collet because the little "flat" can't pass the screw. Just a little "hint" you may be using, or could use in the future.

No argument here Jerry. I haven't checked them lately. The guy they hit in Fla was a shrimper screwing around with a repeater while on his boat. Yea, I also heard his next step is the 11 meter band and related items. Wouldn't surprise me...he's done alot in the last year or so. I neither condone or dissuade freebanding, just folks telling others what to do. Like you said, if noone is bothering you, why give a hoot?

Hello Professor: I stand corrected, on the spelling.

But then again as usual when I pin someone down with the facts, they resort to the spelling thing. And of course don't dare respond technically.

Most of the guys who get all wrapped around the axle over spelling are the types who are through for the day if they brake a nail!

Are you going to Chicago to show em how "efficient" your amp is??????

Hello Ed,

One way to cure the noise is to trade the Ford for a Chevrolet! LOL!
Now that I've finished jokin' with you, I'll tell you one that happened
to me 20 years ago. I installed an HF ham rig in a '68 Chevy Impala and
was plagued with ignition noise. I did the usual filters, plug wires,
chokes, and caps, and nothing worked. I knew that the noise was being
radiated into the air because when I removed the antenna, the noise
went away completely. I was stumped. I was driving along one day and
happened to notice that when I applied the brakes, the noise disappear-
ed. Funny, I hadn't noticed this before, but everytime I put on brakes,
the noise stopped. I went home and "smoked" this over for a while. I
KNEW something was transmitting this noise to the rear of the car, but
what? Curious, I removed the taillight lenses, and took out the bulbs
one by one because I was intrigued as to what the brakes had to do with
the ignition pulse. When all the bulbs were removed, so was the noise.
Hmmmmm..... Eureka! The noise must've been traveling along the wiring
harness and onto the antenna via the taillight filaments. I went to the
hardware store and got some plain metal screen door mesh. I cut this
wire screen to fit behind the taillight lenses and carefully screwed the
lenses and the mesh back on over the bulbs, effectively grounding the
whole fixture--a "grounded" grid, if you will. IT WORKED! No more
noise. The radio was quiet as could be.

Just thot you'd like this little experience--especially since I made a
smart aleck remark about Fords! LOL!

I always put a switch on my amps to control the delay. There is a
470 to 1000 mF cap near the big relay. Lift one leg and wire in a
switch. <: You can use a three position switch and make a long and
a short delay.

Postman Pete wrote:

Easy there prozac, if you run the simulations you will find by selecting the door not opened by Monty will have the car two out of three times. Where you are going wrong is by assuming that Montys action by showing a door with a goat is not taken into account. It has to be! Its key in understanding how the odds play out. He CANT open the door with the car in it, so he is restriced in which door he can show you This plays into the logic of knowing wheather or not to change your pick of doors. Its called "the theory of restricted choice". In any case, even forgetting about theorys, if you take the time to run the simulations you will find that 2 out of 3 times its best to change doors, always, it never varies... never.

>Read this and read this carefully. Once the third door is opened it is no
>longer part of the odds. The host asked if he wanted to stay with his first

Message-ID: <20000821215039.08145.00000137@ng-bh1.aol.com>
Source record: 49381

i am thinking of installing channel guard , but from what i read , they haveseperate filters are for am/fm and for ssb . so if you use am / and ssb equally you would need to get both filters , dumping 60$ + tech costs ......

what i don't understand is both AM and SSB on my radio 10.695mhz IF filters , and am has a 2nd 455 khz IF filter . why won't the 10.695 work on both ?

has any one here put a channel gaurd in a delta force ? , if so tell me about it .

and yes , i am 100% clueless about the internal working of a radio , i just wanna know which ones to buy

That is what attracted me to this NG.

All the polite, well mannered, well versed and read individuals that come
across my monitor.
I just can't wait to see the next bunch of headers when I log on. The
command of the American\ English language by certain individuals (Don't
blush you know who you are) is truly amazing.

I had one and it did about half of what it was rated for. After replacing the transformer, Adding 2 more pass transistors, Heavier diodes, Bigger and better filter caps and an in-rush protection circuit. it turned out ot be a fairly decent power supply.

2993. Thiers a new amp in TOWN

Tango Is the best! Tango class C thing or you ain't got that swing! 4 pills -32 2sc2879's! Soon pics with covers off 50ohms in 50ohms out! New transformer setup that blow the comp amps out of the sky! Clean loud proud modulatin get down and do the TANGO! Who wants a TANGO I said WHO WANTS A TANGO!!!!!! KEYDOWN KEYDOWN WITH A TANGO FOR THAT EXTRA EDGE ON THE LINE! Put your money where your mouth is! It pays to be a sandbagger! The great thing is I didn't steal someones design! Thanks To Uncle Sam for his investment in me!

In MY DREAMS THis is Just a dream

This amp does not exist

dude you have all wrong i did not say 55 wasn't any good i said how others
brag and glory the 55's antenna against the monky
whith out undestanding why well i'm going to tell this newsgroup why55's use 3
turn coil a lot of guys run 5to 6 turn coils =3turns more metal in the air
better receive &transmit so when the guy with 6turn coil
put a 55 3turn coil he notice it right away whith out undestanding why he now
has more metal in the air but you bunch of ebonic air heads know it all can see
this
to understand what just happen istrue is true just your basic antenna theory
1o1

The point is why did he have to resort to coming to this NG for a prompt response?

The internet is a new frontier for mail order and there are to many horror stories of people being taken advantage of. Merchants on the internet have to strive harder and communicate better to avoid people thinking the worse.

EXPORTSRUS has always had a good rep on this NG but your response seems to create problems for you.
Just my 3 cents.

again antenna theory 1 o 1 center load is better than base and top load is
better than both and fighting stick or 102 in steel whip
better than coils. 3 turn coil better than 6 turn coils ans so on is true is
true get rid of ebonics and get hook on phonics you might learn something

oh geez, one more thing, so a 102 inch whip is better than a coil, well
that is most interesting . seems like this subject has come up a time
or two on here, so are you saying i could pull up to , i believe what
you folks call the line in the , (he, he, he) killing field, and ah ,
lets see, oh i could stomp a electronic mudhole in that thing that
passes for a truck in texas, you know, peak a boo hoo hoo's truck with
that silly contraption he calls a antenna ,...can you
smellllllllllllllllaaaaaaaaaaaaaaaaaaaalalalalla , what curious is
cookin,.....cd is out.......

Jay,
Why would I bother discussing anything technical with you? If you were as technical as you think... we wouldn't be having this conversation... because you would know that a tuned amplifier is certainly capable of the 75% efficiencies I mention. You sir... are a technical fraud... and I believe most out there know it. As far as the spelling... no... it doesn't mean all that much... but it gives me some insight into your character. One who spells like you do either knows how to do it right and doesn't care or really doesn't know how to spell. Which are you? The guy who has low self esteem and doesn't care or the dummy who never learned?

Nope TNON it is 50 / 50 and will never change, the first choice has nothing to do with anything because the results of the first choice will aways be the same no matter which door you pick. . It in no way effects the final outcome. You will always wind up standing there at the second choice picking between 2 doors. One has the car and one has the booby prize. The odds will always be 50/50 that you will get the car. You need to borrow my tractor.

Once one of the goats is revealed you are faces with two door one with a car
and one with a goat end of story. 50/50 chance no matter how you look at it
the door you pick either has the car or the goat this is so stupid just end
it.

Reread the last line below. This deals with what can, and cannot be
built/use/sold for US/FCC licensed Amateurs. There are certain features
that a legal amp cannot have.

> Charles Davis wrote:

This is a little humor I found that kinda follows this same "N vs S" thing.... check it out...

Twelve things NOT to do in the South.

1) Don't order steak at Waffle House. They serve breakfast 24 hours a day, so let them cook something they know.

2) Don't laugh at southern people's names. (Merleen, Bodie, Luther Ray, Tammy Ann, Mari Beth, Inex, etc.)These people have been known to beat a man's ass for less.

3) Don't order a bottle of pop or a can of soda. This can lead to a beating. Down south its called Coke. It don't make a damn whether its Pepsi, 7-Up or whatever else, its a Coke.

4) Don't show allegiance to any college football team that isn't in the SEC. Tennessee, Alabama, Mississippi, Georgia, etc.) All the others are just a bunch of pansies that play teams like Wyoming.

5) Don't refer to Southerners as a bunch of hillbillies. We know our heritage. Most of us are more literate than you (e.g. Welty, Williams, and Faulkner). We are also better educated and generally lots nicer. We have plenty of business sense (e.g. red Smith of Fed Ex, Turner Broadcasting, MCI Worldcom, MTV, Netscape). Naturally, we do sometimes have a small lapse in judgement (e.g. Clinton, Fordice, and Duke). We don't care if you think we are dumb because we will kick your ass.

6) We are fully aware of how high the humidity is, so shut the hell up, spend your money, and get the hell out of here.

7) Don't order wheat toast at Cracker Barrel. Everyone will instantly know that you're from Ohio. Eat your biscuits like God intended and don't put sugar on your grits.

8) Don't fake a southern accent. This will insight a riot.

9) Don't talk about how much better things are at home because we don't give a damn. If you don't like it here, take your ass home.

10) We don't play lacrosse, hockey, or any of those other sissy northern games, so don't come down here asking the score because we don't give a damn.

11) We know how to speak proper English. We talk this way because we want to, and because we can. We don't care if you don't understand what we are saying. All other southerners understand what we are saying and that's all that matters. Now, go home.

12) Last but not least. DO NOT come down here trying to tell us how to Bar-B-Q. This will get your ass shot. You're lucky we let you come down here at all. Question our Bar-B-Q and go home in a pine box

There are never really more than 2 choices... Regardless of the door you pick, Monty will ALWAYS show you one without the prize... doesn't matter what the door's number is. He won't open the one you chose, and he won't open the one with the prize. The third choice never really existed in the first place. Therefore the odds are 50/50 that you picked the right door.

RG 10-6

3029. The Turtle & The Rabbit.

Newsgroup: rec.radio.cb
Date: 2000-08-23 00:00:00 UTC
From: prozac <prozac@bayshorenetwork.com>
Message-ID: <InRo5.18010$e11.128146@news1.rdc1.nj.home.com>
Source record: 49518

Using only the facts I'm about to give you will find that a rabbit would not catch up to a turtle if the turtle was given a head start.

Once the turtle is given a head start the rabbit would have to make it were the turtle was when the rabbit started running but by that time the turtle would have already moved on. Now that the rabbit has noted were the turtle is and makes it to that point the turtle once again has already mover on. Go figure?

You may argue the fact that the velocity of the rabbit would be much faster then the turtle but play with the above facts and you will see the rabbit will never catch up.

more N vs S humor ***

Notes for Yankees relocating to the South...

Save all manner of bacon grease. If it can't be fried in bacon grease, it ain't worth cooking, let alone eating.

Don't be surprised to find movie rentals and bait in the same store.

Do not buy food at the movie store.

Remember: "Y'all" is singular. "All y'all" is plural. "All y'all's" is plural possessive.

There is nothing sillier than a northerner imitating a Southern accent, unless it is a Southerner imitating a Boston accent.

People walk slower here.

Don't be worried that you don't understand anyone. They don't understand you either.

The proper pronunciation you learned in school is no longer proper.

"He needed killin'" is a valid defense here.

If you hear a Southerner exclaim, "Hey, y'all, watch this!" stay out of his way. These are likely the last words he will ever say.

The winter wardrobe you always brought out in September can wait until November.

If there is the prediction of the slightest chance of even the tiniest accumulation of snow, your presence is required at the local grocery store. It does not matter if you need anything from the store, it is just something you're supposed to do.

Florida is not considered a Southern state (except Gainesville). There are far more Yankees than Southerners living there.

As you are cursing the person driving 15 mph in a 55 mph zone, directly in the middle of the road, remember, many folks learned to drive on a model of vehicle known as John Deere, and this is the proper speed and lane position for the vehicle.

Just because one can drive on snow and ice does not mean you can't stay home the two days of the year it snows.

If you do run your car into a ditch, don't panic. Four men in the cab of a four wheel drive with a 12-pack of beer and a tow chain will be along shortly. Don't try to help them. Just stay out of their way. This is what they live for.

You can ask a Southerner for directions, but unless you already know the positions of key hills, trees and rocks, you're better off trying to find it yourself.

Hello all, I just wanted to share some information with my fellow collectors of "Vintage" CB gear, this guy is what I would classify as a "Master Tech" for Browning and Trams ONLY, he is very fast with his service turn-around time, and extremely careful with repairs, and packaging of radio equipment. the companies name is; Barkett Electronics, and he's in Trinity Alabama, (256)-350-3848 and his name is Greg.....just a pleasure to deal with, I know its getting harder and harder to find competent techs to tune up and work on these "Classic" & "Vintage" sets, but this guy is by far the best ive seen, in a long time. I hope this info will help some of you out there, and I am in NO-Way affiliated with Barkett Electronics or Greg, thanks and best to all.....
Frank in Connecticut.
"CONTROLLER" (AM) Transmittin on 40 @ A Time, On My D201's "Wave's"
"Sideband Omni Broadcaster 52" (SSB).....Keepin it within 20 With My PEP.

Hi James, I think that the Cross field antenna has been debunked enough times that it can be dubbed a farce. But if you have a working 12" model on 27 MHz. I would be glad to run a side bet with you on it's claimed performance.

Do you mean the A-99 clone from Valor that they are currently selling?
I bought a case of those sometime back. Out of the 9, 2 didn't work
right out of the box. 3 more failed after 3 weeks in service, after
Valor refused to warranty them I threw the rest away. It seems as
though right before Valor was sold a while back they flooded the market
with a bunch of questionable merchandise, and the current management is
refusing to warranty any of it. Besides just like most of RS's pricing
$69.99 is a bit much for that antenna.

Put the radio in the PA mode (plug an appropriate load into
the PA jack) or open the RF chain signal path so that
there's no high level amplification of the fundamental
27 MHz signal while you perform your audio tests.

with
> a full sized quarter wave antenna that will out perform the shortened
> Monkey Made of my choice in range field strength measurements. It's
> time for you know it all's to put-up or or shut up.

I don't consider myself a know-it-all but I do have a MSEE and work in the
business and would like to think I know what I am talking about. Based on
my knowledge
I wouldn't take the bet. It's not a fair test. No whip will outperform a
loaded antenna of that
design in a FS test.
I also have to wonder if it's a good idea to make bets against/piss
off/insult maybe
thousands of your potiental customers on this NG? Not real smart for such a

smart guy.

The delay should be the same in all modes, and it
shouldn't be that long.

> Is this a settable delay time?

Only by changing a part value or adding a switch to
turn it on and off.

> Also lately I notice it seems to hang for a very short time (around 1
> second) after I unkey on AM too. Anything I can do for that?

The delay should be about a second in all modes.

Between the antenna jacks there is a coil. Just to the
front of that coil is a 33 uF electrolytic capacitor.
Just to the front of the cap is a short trace with feed-
through points at each end. To get rid of the delay,
cut the trace. To make the delay switchable, wire a
switch to each side of the cut trace. To change the
delay time, change the value of the capacitor. Less
capacitance equals shorter delay and vice-versa.

I have a digital picture of the cap and trace if you
need it.

> I'm surprised how hot this little baby can get when you gab on it for
> long. My coax was pretty warm on both my radio end and the end
> plugged in the amp. that sort of surprised me.

The chassis was designed for the more efficient MRF455
devices. The 250 uses MRF454s which are more powerful
and less efficient. In other words, they draw more DC
and waste more of it as heat. Make sure the SWR between
the amp and antenna is not too high, and consider adding
a fan that blows down into the heatsink fins.

> Thanks

You're welcome.

In the first "choice" you've got a 1 in 3 chance to pick the car.
(Assuming that picking the car is the "win" situation. If you get to
keep the goat, you still "win" something...)

Monty then reveals one of the goats, and it's not the door you picked.

Monty then gives you the choice of staying with the door you picked,
or choosing the other door.

You now have a 50/50 chance of choosing the door with the car. Again,
if you get to keep the goat, then you still win something, in which
case the chances of winning are 100%

But you still have a 50/50 chance of winning the car. The first choice
means nothing, because you're given a second choice after one of the
non-winners is shown. The second choice, in this situation, determines
the odds of "winning" the car.

So I stand behind my inital assessment of the situation, and say
there's a 50/50 chance of winning the car.

Hmmm ... sounds like you don't want the test to happen or ... or ...
you wouldn't be experimenting with crossed field antennas would you?
Doc, if he is, be aware a 12 inch antenna may give you a 6 dB stronger
signal (twice the e-field - at far field distances) over a quarter wave
whip on 27 MHz. There are commercial broadcasters using these things
that are (for broadcast band) only a bit over twenty feet tall. The
key here is that an electric dipole is combined with a magnetic
monopole (loop). For some limited info (I have the IEEE write up from
1994) go to antennex.com.

Well, there are a lot of heated discussions going on. Are you, perchance, combining a loop and a dipole? A crossed-field antenna? An 12 inch antenna on 27 MHz is capable of developing twice the e-field of a full quarter wave whip (at far field distances). I have the 1994 IEEE writeup of the thing from the EMC conference in Chicago. Oh yes, they are starting to use them in commercial broadcasting. A 100 KW station had to reduce to 30 KW to bring their E-field down to authorized levels when they switched from a tower over 200 feet tall to a tiny crossed-field antenna only a smidge over 20 feet tall.

Jim,
Go back and read the thing on the CFA again. It was bogus
to start with, and the commercial station reported to be using
the CFA, isn't! Matter of fact, they switched back to their old
antenna system shortly after testing the CFA. The designer
falsified reports, exagerated, just flat lied about the tests
as testified to by the station engineer who was there. If it
sounds too good to be true, it usually is...

Doc, while I am not surprised, there was (and I have) an article on a
compound antenna using a magnetic monopole (loop) and electric dipole
and with proper orientation and phasing it IS possible to build a
vanishingly small antenna with nearly zero loss. This, however, would
not mean gain over a full size antenna. It is simply due to the fact
of the IEEE article and and patents issued that I ASSUMED that the
whole thing was, in fact, true. Thanks for the input.

73s,
Jim

Today it was running much cooler after I made sure my coax connections were tight. Maybe that was the deal with the heat.

I wondered about your comments on MRF455's v. 454's. I know next to nada about this stuff, but I did see that this amp uses 2 toshiba 2sc2290's for it's pills - is this the amp you're thinking of? Are they the source of the heat?

Thanks again!

Has anyone heard about or experienced the Cobra 148NW ST? What other comparable makes/models would be worth considering?

3077. Re: A Challenge For All The Resident Antenna "Experts?"

Newsgroup: rec.radio.cb
Date: 2000-08-23 00:00:00 UTC
From: jamesrhampton@my-deja.com
Message-ID: <8o186b$83k$1@nnrp1.deja.com>
Source record: 49652

Naw, I just saw the reply from Doc. As I told him, there is some truth behind the thing, but apparently people have been fudging their figures on the cross field antenna. There were patents issued, and I DO have an IEEE 1994 EMC convention book where the math and a few other things were presented. Of course, just because the thing can be made in theory does NOT mean it necessarily exists today. Also, even if the cross field antenna works, to produce gain it would have to have some kind of directionality - even if only to compress the signal in the vertical direction. So I think I'll pass on the side bet. I do have a question, however. The test you are proposing - I am assuming it will be in some kind of an open area test site (similar to radiated emission testing)? I'm just kind of curious, since I would assume that if all any loading coil (or capacitance hat) is doing is provide electrical length to the antenna, it would seem difficult to understand how it could perform equivalently to a full vertical. Then again, what would the results be if the antenna was say 90 inches and electrically lengthened to 5/8 wave? I ain't too sure - which is why I wouldn't want to start ranting and raving too much (and possibly loose money?) In any case, have a great day and maybe if someone takes you up on the bet the winner can buy the looser a box of Rolaids or something!

>doors. One has the car and one has the booby prize. The odds will always be 50/
>50 that you will get the car. You need to borrow my tractor.

Do the card version. you'll see the light.

Explanation below

If we just randomly choose a door we have a 1 in 3 chance of
getting the car. This also means we have a 2 in 3 chance of
getting a goat. Since the goat is the more likely choice let's
continue examining the doors with this 2 in 3 odds.

After our 2 out of 3 odds gave us the goat on our initial pick
we can also say that of the remaining doors there is another
goat and a car. Remember that this occurrence (one goat &
one car) happens 2 out of 3 times also.

Sticking with the game, out of theses two remaining doors Monty
will show us a goat. If these two remaining doors consist of one goat
and one car then the answer is simple. Take the last remaining door.
It has to contain a car 2 out of 3 times.

If you play the game correctly (switch) then you have a 2 in 3 chance
of winning. Do the card version. Report the results.

My first wife was from Michigan. Having grown up in Texas I should have known better, but, well, it happened.

At any rate, I took her to a restaraunt in the south for breakfast, and as we were ordering, the waitress (yes, her name was Flo) asked my wife, "Hominy Grits?" My wife, being from the North, misheard her, and said...

"Two or Three, if they're small."

Just my two cents.

3093. Re: A Puzzle for the Group

Newsgroup: rec.radio.cb
Date: 2000-08-23 00:00:00 UTC
From: nick250@aol.com
Message-ID: <20000823175537.09053.00001129@ng-md1.aol.com>
Source record: 49668

Hamm, thats the beauty of this puzzle, it is totally, completely, counter intuitive. I already left a simple simulation you can run for yourself with a piece of paper and a pencile in 5 minutes that clearly shows its correct 2 out of 3 times to switch, so wont waste space and rewite it. The part you need to remember is that the action of the host DOES matter. He is RESTRICTED in which door he can open becasue he cant open the one with the car. Its called "The law of restriced choice". Someone in another post suggested using playing cards. Take two black and on red card. The red one being the car, the black ones being the goat. Run the simulation by yourself or with a buddy. FYI, its been reviewed and used by college probability classes for the past 20 years (infact some one posted a link to a webb site dedicated to this which had links to major universities who had tested this and run the simulations. I looked at the link to the Naval Academy I think it was). Like I said, hard to get your head around this, but when the simulations are run on computers millions of times, they bear out the fact that 2 out of 3 times changing is correct. Ok, I am done with this topic having explained things three times, ummm unless there is money to be made by wagering on the outcome of simulations.

3094. Re: Cobra 2000 problem.

Newsgroup: rec.radio.cb
Date: 2000-08-23 00:00:00 UTC
From: sideband@cac.net
Message-ID: <39a455f1.3705643@news.cac.net>
Source record: 49669

For those techs out there, and all interested parties, I've fixed the problem.

I started poking around the Bias circuit, and found everything there was happy, so I moved on to the ALC and AMC circuits. Remember, I'd pulled R131 out of the radio, and TR26 and TR24 were replaced with new units before the problem started.

I found the same voltage on both sides of D59, and decided to replace it. Once I did, the radio transmits fine on both AM and *SB.

Thanks to those who posted and emailed me with pointers on this. I really appreciate all your help.

73's and all those good numbers.

-SSB

On or about Sun, 20 Aug 2000 22:17:50 -0400, sideband <sideband@cac.net>, using the forum rec.radio.cb did say:

:Ok. It's finally happened, and, without a reputable tech in the area, I
:need to find help for this elsewhere.
:
:Cobra 2000 transmits just fine on AM.
:Sideband, however, my favorite mode, is where the problems are... When I
:key on LSB or USB, all I get is a big SQUEEEEEEEEEEAL. If I talk into
:the mic, I can just barely hear what I'm saying on another receiver in
:the house, but it's scratchy, and the squeal stays.... but here's the
:kicker... The squeel, causing the transmitter to go full tilt (All 18
:watts PEP) causes the radio to BACKSWING from full tilt back to about 16
:or 15 watts.
:
:As I said, the radio behaves normally on AM. Sounds as clean as ever, so
:I don't think it's the audio section. Maybe the balance modulator? Maybe
:the carrier's not being shut off in sideband? I don't know.
:
:Has anyone run into this one before? If so, can ya point me in some
:direction on which components to test?
:
:Thanks in advance.

Source record: 49673

Hey Barry,

You're welcome. There's lots of technology out there we don't usually hear about! It's amazing to me that a satellite can take a picture of a car and even read it's tag number! But it can be done. I find it fascinating, too. Lots of stuff our respective gov'ts don't WANT us to know. The APRS stuff was pioneered by hams, and, like OnStar, it can give you directions to a street, pinpoint a house, and follow an APRS equipped vehicle wherever it goes. I know some ham truckers who are REALLY into APRS and satellite communications. About as close I got was talking to MIR on a handheld briefly, but the QSO was very short.

As to the CB vs Ham stuff, I get my kicks out of talking to people and experimenting. I don't think you'll find provocative posts in the NG from me (unless someone gets on my case, then I might respond in kind). I think the "bandits" on 10 meter thing is sort of like this: Say you lease a piece of land. You find a nice fishing spot on there. By virtue of the lease the fishing spot is yours to use. However, after fishing there a few times, you return to find a motor home on your land and it's driver calmly fishing in "your" spot. You would have a right to be indignant and take whatever legal means to evict the trespasser. So, when the hams find someone illegally "parked" on their "turf", likewise they get indignant and take steps to get rid of the interloper. Obviously, their most immediate and legal step is to "rat out" the illegal station. "Bout all they can do, right? And it goes from there.

Oh, BTW, as far back as 1967, US satellites were good enough to feed info to BOTH sides of the Arab-Israeli war as to troop strength and movements. And, I'm told, we did just that, although I'm not clear on why unless it was feared that siding with one or the other might de-stabilize the Mid East. Probably, US and Canadian, as well as other countries' satellite technology has improved in spades.

Have a fine day and happy radioin'

Source record: 49676

JV,

Well, I'll try (hope I don't regret opening my mouth!). According to existing theory (as it was explained to me), there are 3 resistances present in a coil-type antenna that result in a given impedance. The accepted norm is a nominal 50 ohms. Those resistances are: feedpoint, coil resistance, and radiation resistance. Ideally and theoretically, the nominal impedance of a 27 MHZ antenna will be near 50 ohms presented at the feedpoint such as in a 1/4 wave whip. Add inductance (coil), then this coil resistance comes into play. So if there is actually 20 ohms at the feedpoint, 20 ohms of coil resistance, and 5 ohms of radiation resistance you have 45 ohms--it doesn't have to be exactly 50. And the radio doesn't care WHERE in the system the HIGHER resistances occur, just so it sees around 50. SO! When you begin removing turns off the coil, and adding more radiator, the 2 resistances begin to migrate down towards the feedpoint (where it is more useful). So the coil (center load) exhibits less resistance to the current flowing and performs better than a coil of more turns. There's a lot of argument about 102" whips vs loaded antennas, but this is the way it's SUPPOSED to work. I suspect the opposite can be true according to one's installation, ground plane mass (size of vehicle), and ground integrity.

So, as I see it, you would be correct in your post vis a vis 6 turn and 3 turn coil. Following this, it would seem that the whip would work even better. But due to the factors mentioned above, we don't always get a "perfect" installation.

And now that I have said this, I retire to my musty bomb shelter to await the onslaught!! LOL!

73

The 'key' is the rabbit's stopping at the turtle's last stoping
point.
Even then, if the rabbit's speed 'delta' is large enough, he would be
at
the turtle's next 'stoping point' waiting on him, at some point.

Medical waivers disappeared with the 5wpm test, unfortunately. The VEs are required to make any reasonable accommodation, however, which may be of help to you.

Dick

13. We do not and I repeat do not sip wine coolers or fruity liquors,
however we do drink those grain alcohol products made in Lynchburg, TN
or Owensburg, KY (however we will drink some products from Canada,
provided proper mixings are provided). Coors Beer is considered
inported but we will usually try any beer found in Dan's House of Beer
under $4 a six pack and while free beer may not be my brand, it is free.

14. Mind your manners. (somehow I hafta xplain this one to Yankees all
the time?)

I'm thinking of picking one of these up. Is this a solid radio? Will be using in a mobile application and will be on SSB and AM. There are a few places selling these at a pretty good price so thought I move on it pretty quick.

Anyone heard this radio, how does it sound, Is there any know manufacturing flaws or bugs? I havent heard of any mods for this radio but was hoping to get more channels out of it.

Thanks--

Mike

I almost tend to agree with you, Jerry, on the pirates parking on ten meter, hence my preference of the word "freebander". To me, a freebander is one who talks on the "off" channels, the channels that are not allocated to any amateur. To talk on the allocated channels is to "pirate" and I can empathize to a point the hammies reaction.

Another way to look at it is that there are six combinations and 2 of the six are right so the odds are 2/6, the same as 1/3. Nothing hard about this one.

Disregard my last post, the odds are 50/ 50 that he will pick the car. He gets two independent choices one having nothing to to with the other. On the first choice the selection is narrowed down to 2 choices no matter which one he picks. Monty might had well of given him the choice of 2 doors instead of 3. Had to get out my tractor necklace and wrap the chain around my neck.

3130. Galaxy blue face 250 - settable ssb delay?

Newsgroup: rec.radio.cb
Date: 2000-08-23 02:21:30 UTC
From: postmanpete@sansspam.earthlink.net
Message-ID: <39a333a0.389790024@news.earthlink.net>
Source record: 49557

Thought one of you guys might know this. I've got a little galaxy 250 blue face amp. It doesn't say it's the HD version, but it does have a BIG blue resistor in it.

Anyway, it's got a little too long of a lag for me on SSB. It waits about 3 or 4 seconds before it lets me receive normally.

Is this a settable delay time?

Also lately I notice it seems to hang for a very short time (around 1 second) after I unkey on AM too. Anything I can do for that?

I'm surprised how hot this little baby can get when you gab on it for long. My coax was pretty warm on both my radio end and the end plugged in the amp. that sort of surprised me.

Thanks

3131. Uniden Pro 520 xl -turn down dead key

Newsgroup: rec.radio.cb
Date: 2000-08-23 02:23:47 UTC
From: postmanpete@sansspam.earthlink.net
Message-ID: <39a43479.390006583@news.earthlink.net>
Source record: 49558

Anybody know what I pots I need to adjust inside my little Uniden pro 520 to get it's deadkey down and it's modulation up? I'm trying to use it to drive a little 2 pill galaxy 250 amp and I think it's too high. Looks like it's dead keying around 5 watts. It works okay with the amp on it's lowest setting, but if I crank the amp up, it produces a squeal (or so they tell me).

Thanks!

sounds like the usual modern electric fuel pump "whine" mostly associated
with Fords. There are several posts on how to cure that over the last week
or so..Its VERY likely being picked up through the antenna, so forget the
power leads and filter the power leads on the fuel pump (which are
transmitting that mess to you).. Good luck.

Hi Modsquad and All,

I remember a few years back here in The Motor City here, there was a
dude, the *supposedly* bought a "box" from a local dude here that was
building them, he would go around and start running said guy in the
ground, giving out his real name, address, ect.... trying to say he
sold him a bad unit ect.... anyways, one fine day, he got tired of it,
the guy got a friendly visit from the local chapter of the IRON
COFFINS at his house, beat him and his 21 year old punk ass kid to
bloody pulp, had thier way with his woman, and as they were leaving,
they said, "this is for running your mouth!"

My point?

Sometimes it's best not to be the loose cannon, cause you never know
who knows who, and who's friends with whom....

Actually, I am curious to know how well the Monkey made antennas do as a drive around. The one is close to 8' tall and the others have such large surface area at the coil the wind resistance has to be substantial.

Lets here it from the Monkey made users How are they working and how are they mounted to your vehicles.

maam , i was kidding about the picture , i understand the situation believe me. whenever a woman starts talking that stuff about they have a man that loves them for who they are, wellllllllllllllllllll,,,,,,i get kind of nervous. believe me i have heard this before, and it usually comes from the mouths of large calorically challenged type women, but whatever, if he loves you for who and what you are, then that is sooooooooooooooo cooooooollllllllllllllllllll. i understand the wonderful world of cb radio and for all my experience there has been shall we say , a verrrrrrrrrrrrrrrrrrrrrrrrrryyyyyy, small number of times that i have evvvvvvvvvvvvvvvvvvvvvvvvvveeeeeeeeeeeeeerrrrrrrrrrrrr seen a good looking cb woman, but whatever, it does not bother me, believe me. i do what i do because i like it, what a woman likes is of little concern to me. i am single and there are times when cd is lonely , yes i will admit it. but then i think about the nagging, the whining, the need to change me, the manipulation and the need for me to listen to their incessant psychiactric and financial problems and the bullshit and then i thank the good Lord that i, the one and only cd am single and free of the ball and chain . of course this could change. i the great cd get many , and i do many chances but i shut up. because a good looking woman is nice to look at, but if i started dating her, i would definitely have to get rid of my radio stuff and that , issssssssssssssssssssssssssssss.....not going to happen, not now , not ever. and if you had to blame somebody for this, then you

would have to say that i am disfunctional, and am from a disfunctional family thanks to my dad , who frequents this ng, and that is all i have to say about that. this is the nice and pleasant cd , and i am back in the bushes(and there is nothing wrong with bushes), cd is out.....

I was referring to F layer skip, not sporadic E layer skip. Skip from
the E layer allows communications between the ground wave loss area
and the 300 mile F hop. Less common skip can be ducting, heat inversions
and meteor trails, although these methods affect VHF and UHF more.

Ok.
I trade in radio gear, from old/collectible military gear to
heathkit HW-101, to things like the National NCL-2000 linear,
etc.. basically your ham gear, which does include some homebrewed
linears from time to time. I've got the usual FCC general
radiotelephone licence that says I can work on the stuff.

So, am I breaking the law because I have 'rf amplifiers' for
sale? Somehow I think that there is a place for legitimate
business here somewhere. I suppose the commercially made models
are type accepted for the ham bands, and I can only assume that
the homebrew ones were built by ham radio guys.. I think there is
a provision that a ham can build one or two linears capable of
operation on 10 meters a year. ??

comments?

. i understand
the wonderful world of cb radio and for all my experience there has
been shall we say , a verrrrrrrrrrrrrrrrrrrrrrrrrryyyyyy, small number
of times that i have
evvvvvvvvvvvvvvvvvvvvvvvvvvvvvveeeeeeeeeeeerrrrrrrrrrrr seen a good
looking cb woman, but whatever, it does not bother me, believe me.

I think you haven't ever seen a good looking cb woman is probably because
you're just not attracting any women. little girls maybe, but not women. a
real woman doesn't look at an immature, disfunctional man. Unless she is
disfunctional herself.
----

and if you had to blame somebody for this, then you
would have to say that i am disfunctional, and am from a disfunctional
family thanks to my dad , who frequents this ng, and that is all i have
to say about that. this is the nice and pleasant cd , and i am back in
the bushes(and there is nothing wrong with bushes), cd is out.....

Nobody is blaming anybody. As for being disfunctional and from a
disfunctional family. You should seek psychiatric help if it still bothers
you to this day. And it seems that you get a lot of attention by putting in
a lot of your opinions in the news groups. That is good "talk therapy".
Anyway gotta run.

From: David Little <dalite01@sprynet.com>
Message-ID: <8nvrr4$u22$1@nntp9.atl.mindspring.net>
Source record: 49583

I think it uses a 33 uF cap for the delay. Most use a 10 uF through a switch. You can vary the size for the length of the delay. Since the Galaxy does not have a SSB delay switch, the delay is active in AM also, causing the long "hang time" before the relay switches the receive back in.

3159. Re: FOR ONCE AND FOR ALL!

Newsgroup: rec.radio.cb
Date: 2000-08-24 00:00:00 UTC
From: cbrs@webtv.net
Message-ID: <27496-39A4E7C5-1@storefull-127.iap.bryant.webtv.net>
Source record: 49621

It's easier to see what's going on if you draw the three possibilities
on a piece of paper. The car is either behind door 1, door 2 or door 3
-- these are the three possibilities as illustrated below:

(C=car, G=goat, X=your door, M=Monty's door)

1)
C G G
X M

2)
G C G
X M

3)
G G C
X M

If you originally chose the car as in possibility #1, then you would
loose by switching. However, if you had originally chosen a goat and
Monty shows you the other goat, then by switching you would get the car.
Possibility #2 and #3 above show that by switching you would end up with
the car, thus the 2 out of 3 odds of winning the car by switching.

Since the RCI 2970's are selling $225-250 in EC, I would suspect the 100w 3500 to run $200-225 in EC, the 30w about $150-175 EC.

3164. Digital SWR Meters

Newsgroup: rec.radio.cb
Date: 2000-08-24 00:00:00 UTC
From: Richard Smith <rsmith@planeteer.com>
Message-ID: <Lt8p5.54285$qS3.107927@tor-nn1.netcom.ca>
Source record: 49626

Just wondering if anybody has had any experince with one of the digital SWR meters that are around. They look to be handy for mobile applications, as there is no need to go through the FWD/REF procedure every time to check the SWR, and a quick glance at the display is all that is needed. Are they as accurate as the analog meters, and do they have the problems that many analog meters have associated with SWR changing with increased power level etc.

Thanks,

Richard.

Calm down, dude... your question led him (and the rest of us) to believe that your were interested in getting the best performance you could. Well, that being the case, your antenna would not give "the best performance" regardless of where you put it. That is why he suggested a different antenna... he wasn't slamming you, he was just giving a suggestion.

As for where you mount it, the only thing that matters there is aesthetics. The whole truck is your counterpoise because its all grounded. Just put it where you think it looks good. I put mine right above what would be the separation from the front and rear parts of the cab, but mine is a permanent mount Wilson 5000. It looks a little different. =)

DX88, stock mike/bracket/mount, in great working order, no "super mods" noise toys or other Golden Screwdriver work done, shows normal wear from mobile use (mounting bracket scratches, etc.), just a nice, good running 88 with all of the Galaxy stuff on it (AM/FM/SSB/zillion channels/Freq. display, echo, etc. etc.),

1st $245 prepaid MO only gets it shipped to the door USPS insured priority.
Will consider trades for 11m/2m/scanners etc.
Email replies please

Bill My point is you went thru #12 to fix a problem the average Joe cber will not get a hold of him unless they know him or someone is closely associated with him.. As i said your only reason for getting ahold of him was because his product was not performing as expected... Do you call him personally when you order amps ? If you do you are lucky since 99% of the people have to go thru xportsrus ..

nice PC76 Uniden (same as the original 29LTD) 40 ch AM mobile, connex dual pot
echo board in it, no extra holes, peaked and tuned for loud audio and good
swing, stock mike, nice rig for $85 shipped to your door via USPS insured, ppd.
MO only,
email replies please.

Not to flame anyone, but I have my antenna on the back of the mobile and
it is directional to the point where I can select who to talk to if
there are many stations in many directions.

I would be curious if someone could test a Wilson 1000/5000 or K40 base load antenna (both are around 5 1/2 ft tall) against a cheap $20 4 1/2 or 5 ft top-loaded fiberglass "stick" , such as a firestick. Both antennas of course would have to be mounted in the same place on the same stationary car & tuned, say, a mag mount on the roof for both. I wonder if the load being so much higher would more than make up for the fact that it is narrower & smaller gauge......My guess is that under the same mounting conditions, there would be no difference or even a slight edge to the top-loaded firestik.....Any "Antenna Range" testers out there able to take that one on???? I'd also like to see field strength differences between a Wilson 2000/5000 "trucker" & a 5' top load stick under the same conditions.....Time to see what is myth & what ain't.....

3189. Re: palomar225 back swing HELP!

Newsgroup: rec.radio.cb
Date: 2000-08-24 00:00:00 UTC
From: fire228@my-deja.com
Message-ID: <8o3odl$55m$1@nnrp1.deja.com>
Source record: 49701

******

The motorola MRF455 and the SD1446 are typical devices in this particular amplifier. (Palomar 225) A single device has the following specifications....

4 RMS watts input @ 12V. @ 27MHZ will produce approximately 88 watts RMS output. (All tests are carrier only, unmodulated)

Bill wrote:

The 225 is really only a 40-50 watt amp when using average reading wattmeters. (This is bull) With 2 of the devices mentioned above, 8 watts RMS input will produce 170 - 180 watts of RMS output. The nomenclature on the front of the amp is more accurate than you know.

I regularly order devices from RF Parts. Whether it's a single device or a matched set of devices, RF Parts always marks the test specs on the envelope in which they are shipped. I often wondered how accurate my own test bench setup was, so i decided to see if I could duplicate the results that RF Parts came up with during their tests. With the figures quoted above, I created the exact conditions to test a pair of MRF455s.

I adjusted the dc rail to 12v. and set up a transmitter to produce 8 watts of RMS carrier, as measured with my equipment. With 8 watts of RMS power into a Palomar 225 with a pair of MRF455s, I saw between 175 - 180 watts RMS output. I was gratified to see that my bench setup was at least as accurate as the bench on which these devices were tested/matched.

Bill, I applaud you in your effort to reconcile the fine art of rf power measurement with the plethora of test equipment currently available on the market, but I would suggest that anyone who depends on accurate measurements of rf power output should use great care in setting up their test bench and check the accuracy of same with some kind of industry standard. While the above power levels/measurements are only useful in FM operation, I have found that by favorably altering the RC time constants in the negative peak clipping circuit, one can produce basically the same results in AM operation as well. (Radios using transformer derived audio only) To read a discussion I had recently with the techs at exportradios.com on this very same subject, follow the link below.

Have fun,
Jack

Do me a favor, Punk someone so people will believe a small amount of what you say, as it stands no one knows whether or not you even own a cb. Keep in mind you have made a lot of threats and have never even showed your face, at least not with the handles you use on the NG. You are either scared of confrontation or you don't have 10% of what you claim. Whatever the case may be you sure are good at hiding behind that computer.

3191. WANTED: 1960s Raytheon CB radios and documentation

Newsgroup: rec.radio.cb
Date: 2000-08-24 00:00:00 UTC
From: k5dh@raytheon.com
Message-ID: <Cgdp5.2$jJ5.1150@bos-service2.ext.raytheon.com>
Source record: 49703
Cross-posted to: rec.radio.swap,rec.radio.amateur.boatanchors,rec.radio.amateur.equipment,rec.radio.cb

Greetings from Texas!

I am looking for 1960s Raytheon CB radios and handhelds for my personal collection. I'm interested mainly in complete sets that are in good condition and electrically restorable, but I will consider "beaters", "fixer-uppers" and "parts rigs" also. I already own examples of the TWR-1, TWR-2, TWR-4, TWR-5, and TWR-7, so I'm not really looking for any more of those models (unless I get 'em really cheap, in outstanding shape, or both).

Tube-type Raytheon sets were made by the company's Apelco division in S. San Francisco, CA. I may be interested in some of the similar looking and electrically identical Apelco CB models. Certain Sears (Allstate) and Webster CB radios were made by Apelco, and they would be good parts sources for my Raytheon restorations. For several years, Raytheon also owned SBE, and at least two of the later Raytheon CB models were made by the SBE division.

I am also looking for any kind of written documentation that pertains to Raytheon CB equipment, including owner and service manuals, advertising, spec sheets, dealer catalogs, copies of ads and articles from magazines, and so forth. In addition, I'd LOVE to hear from anyone who worked for Raytheon, Apelco, or dealers who sold or serviced Raytheon and Apelco CB radios. I've already been contacted by a number of folks who've given me bits and pieces of information, and I really appreciate it!

Visit my Raytheon CB radio web site at this URL:

http://www.qsl.net/k5dh/raytheon.html

I have some interesting historical tidbits posted, along with pictures, advertising, and so on.

In addition to running my own Raytheon CB web site, I have been working with volunteers at the Raytheon company archives up in Massachusetts, helping them document the product line (which did not previously exist in the archives in any way!).

Thanks and 73,
Dean, K5DH

You know Bill, this situation between you and Rebel where he gave incorrect info and you corrected him, but in no way flamed him, but he flamed you, represents a big problem of this news group. The idea of a news group is the sharing of information for everyone's benefit. All the flaming that goes on here I am sure scares away people who we would otherwsie would be good contributors. They decide to not to contribute because they don't want to deal with all the Bs. Beyond that, if misinformation is given, someone with the correct information will be reluctant respond because they don't want to get flamed. I have been following rec.radio.cb for about a month now and I have learned some, but man oh man, you sure have to slog through a lot of crap to find the good nuggets.

MHO, Nick

Ive never used the TR 696....

Between the Grant XL and the 148 NWST... My opinion? ST radios suck.
Uniden is good stuph.

Just my two cents.

I will have to agree with SSB the sound tracker radios suck.You can not get the quality of the sound tracker to work unless the person on the other end has it too.The grant is a good radio.That is what is in my car.The Texas Ranger Radios have a copy of the Grant 148 that is not a bad raio either.
Actually it is a copy from what I understand later Mike

The the generally accepted comparison between base loaded ,center loaded and top loaded antennas are correct but with a gotcha' when it comes to CB. Most top loaded antennas use a capacity hat and low loss coils. CB antennas in general do not use capacity hats and the coil is just wrapped around the fiberglass rod and covered with relativly lossy vinyl. This means a top loaded CB antenna will have a lot more wire than the 108 or so inches than a unloaded 1/4wl whip. The lot more wire means more loss. Fortunately not too much loss. Example:

A antenna reduce to 60% of it full length needs about 400 ohms of inductance if it is base loaded, 500 ohms if it is center loaded or 2500 if it is top loaded. Adding a capacity hat lowers it to about the same as required for base or center loading. It winds up being that there is not enough difference between a full size 1/4 wl antenna and anythig 5 ft or longer to even be able to measure. This is obviously very fortunate for those who wish to market ugly antennas

that look like something for space communication. While there is nothing inherently bad about these antennas quite often there price is not justified, some are. They are just well made loaded antennas , nothing more.

THe Texas Ranger "296" series is the 148/Grant design. The Texas Ranger 696/969 is the New 6900 derivative board also used in the Galaxy 949/959, & seems to have a slightly better reciever, better AM & SSB swing & output, and even a marked "spot" for that 2nd final.....

I tried it with my wife playing Monty for 200 times always changing, Came out 97 cars and 103 goats. Tried it 200 times not changing and it came ot 99 and 101. This is close enough to 50/ 50 for me with this small of a sample. Wife won't do it anymore. Am I correct in assuming that Monty knows where the car is and is always going to show you a goat?

>5' top load stick under the same conditions...........Time to see what is myth
>& what ain't..........

I did this test a few years ago (minus the Wilson), at least as best
I could. The problem is that when swapping the magmounts the
position might change a little bit. If the position changes a little
bit then the measured field strength may change a little bit also.
Seeing how all of these antennas are very close to begin with
then you have to wonder if the results may be off just a little bit?

Anyways, I did run the test and attempted to calibrate the results
in db's . The calibration may be off a little bit, but the order from
the best to the worst as I measured IS accurate.

Radio Shack DLX magmount 0db
K-40 ..... .8db
Radio Shack 4.5' center load 1.4db
5' Firestik 3db
6.5" Hustler top load 4db
108' Stainless Steel whip 4.5db
7' Firestik 5db

Of coarse since the time of this test I have found
and measured even better antennas. Of these the
practical ones all use large diameter masting made of
highly conductive material. A large diameter, air spaced
loading coil. This coil is always upwardly located and the
overall antenna height is over five foot tall.

>won't do it anymore. Am I correct in assuming that Monty knows where the car
>is and is always going to show you a goat?

Yes, Monty will always show you a door with a goat.

You did something wrong. Alternate between swapping and not
swapping for every deal. You will find that you will be twice as
likely to win with your swapping deals.

The explanation again:

If we just randomly choose a door we have a 1 in 3 chance of
getting the car. This also means we have a 2 in 3 chance of
getting a goat. Since the goat is the more likely choice let's
continue examining the doors with this 2 in 3 odds.

After our 2 out of 3 odds gave us the goat on our initial pick
we can also say that of the remaining doors there is another
goat and a car. Remember that this occurrence (one goat &
one car) happens 2 out of 3 times also.

Sticking with the game, out of theses two remaining doors Monty
will show us a goat. If these two remaining doors consist of one goat
and one car, as explained above, then the answer is simple. Take the
last remaining door. It has to contain a car 2 out of 3 times.

>Silly boy, amps aren't allowed on the CB bands.
>

What an odd reply. Of course they're illegal on the CB bands... I for one detest the use of amps on 27 MHz, I find them to do nothing but add noise and splatter to the band, at least in my area.
But this reply is lame. Amps may be illegal but they're available across the continent, and whether one agrees with their use does not presuppose a need to stifle the wants of others.
Seems like a baiting post to me.

I know, Jerry, and I don't want to open it all up again, but I really think it IS quite bad for people to think coax length makes a difference... just as I think it's bad for people to believe in astrology, or accept every Weekly World News story as fact.
The point is, it's false, it makes people waste their money and time, and it plays into the hands (and bank accounts) of unscrupulous manufacturers and repair people.
It's a bad thing to believe in and promulgate a falsehood, and when I see it happening I usually respond to it. I know YOU don't believe the coax myth, but allowing others to spread it is accessorizing to the crime... you bad criminal you! :-)

3223. Re: palomar225 back swing HELP!

Newsgroup: rec.radio.cb
Date: 2000-08-24 00:00:00 UTC
From: Bill Eitner <kd6tas@netzero.net>
Message-ID: <39A598E7.94728EFD@netzero.net>
Source record: 49735

My statements assumed a symmetrically modulated AM waveform.

You'll never see 170 to 180 RMS (an inaccurate term in itself, you should use the term "average") watts using a pair of 455s or 1446s with anything close to symmetrical modulation. In fact, it's a huge stretch to say that they'll do 170 to 180 average watts even with huge amounts of negative peak compression. You can make an average-reading meter say 170 to 180 watts using a single frequency sideband input signal or a FM carrier, but we're talking AM here. You completely missed that in your excitement over thinking you were going to prove someone wrong.

Based on what you say here, I really doubt that you know the difference between average and peak wattage measurements as applied to the relationships in a standard AM signal.

It's very obvious that you don't know who I am, what I know, or what test equipment I have at my disposal. You have that cocky yet misguided exportradios.com attitude that will come back to bite you in the ass time after time if you hang around long enough. Something for you to remember is that we're not all loser hacks that are condemned to work in truck stop CB shops with little more than a Dosy meter. That's the export-radios.com assumption that's totally false. You'd be well served to distance yourself from that misguided belief.

It should be pointed out that, for a single radiating antenna, coax length doesn't matter.

However, for a cophase system in which the radiating elements cannot physically be placed 1/2 wave apart, the length of the coax can make a difference, allowing the phasing of the two antennas. Of course, this gives you a "fake" beam antenna, directional on the plane created by the antennas, but for some this is the desired effect.

Now that I have my A99 up in the air, with 50ft of rg8 attached to it, there is now a problem.

50 ft of coax isn't enough to go around the house . I knew I shouldn't have added those extra masts. :P

Is there any serious problems that might occur if I use a coupler and connect an additional length of rg8?

Thanks!

Hamm, yes you are correct that Monty knows which door is the car, therefor he will never turn over the car, he will only turn over a goat. So when you wife your acted as Monty she would have had to look at the cards and always turned over a "goat".

Another way to look at it is with pencil and paper. Draw three doors on a peice of paper and mark one with the car in it and mark the other two with goats. Now choose one of the three for your initial "guess" as to the one with the car. Lets say you guess door two. At this point Monty shows you a door with a goat in it and offers you the chance to change your guess. If the car is behind door two, the winning move is to stay. If the car is behind door one, Monty whould have shown you door three with a goat in it and the winning move whould be to change your pick to remaining door, door one. If the car is behind door three, Monty would have show you a goat in door one and the winning move would be to change your guess to the remaining door, door three.

Two out of three times the winning move was to change doors after a goat was shown to you. Like I said before, its counter intuitive, but if you put down on paper and try different combinations of where the goat is and where the car is, as long as Monty shows you where one of the goats is after you make your guess, you will see the change is best in any combintion. Another example bellow.

Door one: Goat
Door two: Car
Door Three: Goat

You guess door one. Monty shows a goat in door three. Winning move, change to door two when given the chance.

You guess door two: Monty shows you a goat in door one or three. Winning move, dont change.

You guess door three: Monty shows you a goat in in door one. Winning move, change to door two when given the chance.

Found in pawn shop today a Hp-125 Penetrater (thats how its spelled) front has am/ssb switch and a rcvr switch which when activated kills all recieve (?). Anyone have any experience with one of these?
It tests 125 watts on cheap Rat Sh--- pwr meter. Also front says " amateur bi-linear" bottom says Amcomm, Fort Lauderdale, FL.
Thanks,
Ken

I appreciate all of the feedback.

It's tough evaluating these CBs on features alone. Talking to others
who have experienced them firsthand saves a lot of grief (not to mention
a few bucks.)

As far as the ST, does it just not work, or does it actually end up
degrading the quality to below those CBs that don't have it to begin
with.

Anyone else, let me know your opinions.

73's,
Cowboy

Bill,

I know who you are and quite frankly, I don't care!

Who is Bill Eitner?

The FCC sent a Warning Notice August 18, 1999, to Technician licensee
William A. Eitner, KD6TAS, citing information before the Commission
alleging that, as recently as July 25, 1999, the licensee was
deliberately and maliciously interfering with K7IJ repeater operations
in his area. FCC Legal Adviser for Enforcement Riley Hollingsworth
reminded the licensee that such operation is contrary to the basis and
purpose of Amateur Radio, degrades the service for legitimate users and
cannot be tolerated. Hollingsworth requested that the licensee contact
him to discuss the matter.

Does any one else?
Jack

http://www.angelfire.com/az/firecommunications/

If someone proving you wrong is what you're looking for, I can provide
that for you as well.

As for RMS being an inaccurate term, you seem to have no trouble
equating the two of them on your web site when you wrote:

"The most common type of RF power meter is the "average-reading"
meter. For our purposes RMS and average are the same".

Which is it, Bill? Make up your mind, Bill.

You seem a little double-minded and hypocritical to me.

I have had all of these radios, I sort of dependes what you are going to do with the radio, If you are going to use a Amp with the radio then the a cobra has the most potenial used with a preamp because it has 4 different tone settings and better filtering than the 696 The Grant will be the loudest and the696 you can get the most watts out of, if you are just going to use the radio then my choice would be the grant for SSB and AM because you will be able to talk to
most stations you can hear when there is no skip. Hope this is of some value to you OLDTIMER.

Richard,
Digital SWR meters are as accurate as the analog meters. I've
tried using one, but I wasn't real happy with it. The changess in
meter readings tell you a lot, and a moving needle tells me more
than changing numbers. Nothing wrong with the meter, just personal
preference...

I conceded the DX came rolling in here across the state, it just isn't all that usual , doesn't happen a whole lot. West is west, so what? just 'cause it's running to California don't mean it's running to Tampa Bay! The bowl was noisy and we dropped to ch. 3, so you tell me who I talked to in Daytona. Maybe those conditions were in conjunction with the storms 'cause the last time I had propagation like that (N,S,E,W AND the short skip) there was a tropical storm in the Gulf. I was told (I didnt check to verify) the mean sunspot was 86, if it matters.

full wave loop (ft) = 1005/ f(MHz), there is no foreshortening effect with
quads.

Easiest way to match the 100 ohm feedpoint is with an electrical quarterwave
of 75 ohm coax.
length (in) = 3015 x velocity factor of coax / f (MHz). Look up
'Q-section' in a good reference.
No need to fool with baluns.

If you build a multi-element quad (a loop and reflector are a good start)
maximum forward gain and best front-to-back will not tune at the same spot
so take your pick. Build the reflector the same size as the loop and
stub-tune it or use 1030 instead of 1005 and slop it in.

Some folks like triangles (Delta Loops) as well. Same formula applies.

Good Luck.

Dick

3252. Re: No Wonder Why Hams Are Pissed

Newsgroup: rec.radio.cb
Date: 2000-08-24 00:00:00 UTC

I knew someone was gonna call me on it. Yes, the frequencies are allocated to other services, BUT, they are almost in non use. As someone stated a few months earlier, there are a FEW, VERY FEW that are being utilized out of the bands in question. Technology has surpassed most of the communication modes on those bands.When the frequencies were allocated, the sophisticated methods of today that prove more reliable did not exist or they were not in use. There is always more traffic on the ham bands than on those frequencies. My scanner is on and wide open at all times when I am home and I can count on one hand how many times I have heard ANYTHING on those bands in the last 12 years that actually may have been legitimate and still have a thumb and a finger or two left over. Someone once told me that just because I can't hear them doesn't mean they're not there. Maybe, but highly doubtful. I did talk to a US Forest Ranger in Burns, Oregon (I think that's where he was, I'd have to check the log to be sure) years ago and he said he waited for the skip almost nightly. Yea, I know it's still a form of squatting, but you can still homestead in parts of the US, and also legally "steal" property if a landowner is negligent. Apples and oranges, I know, just trying an analogy as example.

Should have mentioned that your best element spacing for a two-element is about one meter, something in the 36-40 inch range. Quads are sloppy.

Depending on your use, a quad is fairly strongly horizontally polarized but the X supports handle ice and water a bit better. If you work a lot of local mobiles, you may want to go diamond-shaped and accept the mechanical problems. Your call.

Beaker,
Unlike you, I am not a true radio dork. I only use the radio when on a road trip heading out west to go hunting. It comes in very handy and I meet a lot of great folks on the road that I otherwise would not talk with. I didn't ask about a "better antenna." Pull your head out of your ass and get with the program. It's people like you in these newsgroups that turn people away from a hobby that you obviously like. I realize that I didn't get the "best antenna money could buy" I got an antenna that would meet my needs. You obviously can't answer my questions clearly and in an educated manner when it comes to CBs, but I extend the offer to you that if you have a question about hunting or fishing, MY area of expertise, I would be glad to give my opinion and share my knowledge. Bill:

Think what you will.. There are mutilple types of dyslexia. Perhaps you should do some research on the subject before you go spouting off like this...

I recall an episode of Matlock (Ok.. I was visiting my grandparents, so no snickers from the peanut gallery) where one of a set of twins was dyslexic. The actual murderer was the dyslexic one. The dyslexic one had described the room where the murder happened to his twin brother, who was trying to cover for him. They got tripped up. The non-dyslexic one had described a painting of the "Charming Man" to the police... in reality it was "The Marching Man"

Note that letters weren't juxtaposed here, rather entire syllables were swapped. Charm - March.

Other types of dyslexia cause people to see things "upside down", or reversed, as the "r" in Toys R US.

Other types of dyslexia affect how things are heard. I am, unfortunately, a victim of this particular type... I'll hear words swapped around, in a kind of a "Spoonerism", yet I'm an avid reader. Hell, I knocked "Battlefield Earth" out in a little over 3 days one summer as a child.

So before you open your mouth as an expert in a field, be sure you know what you're talking about, lest a pair of shoelaces pop out when you try to speak.

Just my two cents.

-SSB

This pertains to the PC-78LT....
If you remove the bottom cover (spkr side), with the front of the rig toward you, you will see a small circuit board in the right front area, right behind the front chrome bezel. This is the DSC board. On this board you will see a small (<3/8") metal trimmer. This is used to set the cutoff level of the auto squelch. The usual setting is about equal to a "S9" or so...carefully adjust this trimmer to make the squelch break-level more or less. This same board is used on other Uniden rigs, but in a different location. Be very careful adjusting this trimmer, as it is quite fragile.

While I tend to agree with Bill for reasons I have been rather loud in proclaiming, give me some honest figures and I will begin to buy the claim.

All figures with good 30 MHz lo-pass filters in both the input and output lines; No credit for trash.

1) With the positive power lead grounded, both carrier only and single-tone 100% modulated power output readings.

2) with plus on, same figures.

3) Decent voltage and current readings specifying the gear used and the meter readers.

Surely in Chitown you can find someone of some credibility to confirm the breakthru and sign your nomination for the Nobel Prize.

For horizontal, the feed point should be at the bottom. For vertical connect at the side. The most important thing with a Quad is the "Wire" element lengths. Make the wire as straight as possible and make them 1/4 of the total length of wire. The total length of wire will be determined by the frequency you plan to use it on. To the eye it looks like a dead short but it presents a load to the amp.

Driven element is 1 wave length ... 984/Mhz
Reflector element is 5% longer than the Driven Element.
Director element is 5% shorter than the Driven element.
Spacing is from 0.06 to 0.25 wave length.

Impedance of driven element alone is approximately 100 ohms,
depending on height.
Adding elements (reflector/director) lowers the impedance.

Doc, the 984 assumes the usual foreshortening you get with dipoles. Loops don't foreshorten so that's why I used 1005. The Handbook gives 1005.

The mechanics of a quad can rapidly get out of hand so I suggested 0.1 wavelength spacing. Optimum is supposed to be .15 or about a 6 foot boom at 27 MHz. Speaking of mechanics, how do you mount a 3-element quad? :-)

Dick

3297. What exactly is an AB-1 amp?

Newsgroup: rec.radio.cb

Richard,
Your right, the 984 does assume there is some foreshortening, which I've found holds true for a 'quad' as well as other types of antennas.
A three element quad isn't as easy to mount as an 'even' number of elements quad. There are a couple of alternatives. One is to stagger the spacing between the elements to allow room for a mast. Another is to 'weigh' one end to balance the quad, although this isn't the 'best' idea in the world, all you need is more weight in the air. I guess that's why you don't see too many 3 element quads.
'Doc

3302. ? Need Help Deciding on Gear ?

Newsgroup: rec.radio.cb
Date: 2000-08-25 00:00:00 UTC
From: Paul Watkins <pwatkins@msn.com>
Message-ID: <8o69be$307t$1@thoth.cts.com>
Source record: 49819

Hello rec.radio.cb ,

To give you some background about me, I am a mechanical engineer and I love gadgets and I just purchased a '00 F250 XLT Crew Cab 4x4. I want to install a CB. Sometimes friends who I am travelling with or just listen to what ever. I want to have a GPS, CB, and maybe a scanner in the truck.
I have already bought, but not installed, a Garmin Colormap Street Pilot GPS. I am waiting to install it when I have my radio and maybe a scanner, so I can install all of them together. I also have a combination altimeter/barometer and thermometer for the truck also.
I was considering a Cobra radio because I am familiar with the name, my Father has one in his Ford. On the Cobra 148 NW-ST I like the 12W SSB feature but when would a recreational CB'er use the SSB mode? Would this be useful to extend range if you are out in the back country and need to call out on channel 9 in an emergency? I also like the Cobra 29 WX-NW-ST because of the automatic weather alert even if the radio is off. Could some of you with experience give me some insight on what is useful, thanks.
I was also thinking about the possibility of a mounted scanner. I have heard this is illegal in California, is this true? If it is illegal, do people do it and get away with it? If it is illegal, what are the penalties? If it isn't illegal I was considering the Uniden BC780XLT, any comments. I like the BC780XLT, Uniden says it has continuos band coverage and it is a trunk tracker, I would like to be able to listen to CHP/Police/Sheriffs when I am traveling. When they say continuos band coverage, does they really mean 800 MHz and cell phones and things like that or do you have to do mod's to get those bands?
I can probably figure out the questions above but here is where the real questions start so I can make efficient use of my system. If I mount both units in the truck can they be installed under the dash, or do they need to be installed in the top of the cab so the antennas and radios have the same ground plane or can I just run a ground strap to the cab, or to the roof of the cab? What special precautions need to be taken when mounting the antennas to the roof of the cab? Can the antennas be next to each other or do they need to be separated, if so how much? I will have the GPS antenna on the roof also? Now for antenna selection, I was considering using the Cobra HighGear HGA 450 RD (Red) 4 1/2ft. fiberglass whip antenna. Would this be a good choice? I am not looking for the theoretical best, but I want something that will work well. I just want the components of the system to be matched.
One more antenna question is, as someone else asked, where to mount it on the cab? I believe the advice to him was if you mount it toward the back of the cab due to the ground plane the antenna will be slightly directional to the front, is this correct? I know there are so many variables but what would approx. front and rear ranges be if the antenna was mounted in the

front, center, and rear of the cab under standard operating conditions? On the CB, I also want to use the PA option but I can't find online any sources for the PA speaker. I found a few general PA speakers and their rated wattage, but I can't find any info on the PA power output for the radios I mentioned to be able to select a speaker. Do I need a amp to boost the radio PA output to the speaker? If I do need an amp, how much power would be necessary to be able to be reliably heard over the engine and road noise into the air conditioned music blasting cab of another vehicle? What about mic's, is the Cobra Noise Canceling Power Microphone CA-77 4 pin a good choice? What is the point of a echo mic?

Thanks for the info

Paul I will give you my 3 cents. Go with the Uniden 76 XLW sometimes
available at www.Uniden.com Cobra is not what it used to be. If you can
find a good tech to tune that 76 right you can get over 50 watts output by
changing the driver and the finals.
I found SSB in a mobile a pain. Most of your traffic will be on 17 & 19 on
the highway anyway.

I assume you don't want to drill your cab so go with a Wilson 1000 Mag mount
antenna.
If your going to drill the cab then go with the Wilson roof mount you won't
go wrong with either
Scanners in vehicles in most states are Illegal but someone from CA will be
able to tell you better.
The Cobra Mics aren't very good either try the Astatic or Road king noise
canceling mics.

Somebody a while back posted the URL of a website where you could buy and sell CB and radio equipment that Ebay is not keen on having listed.

Could somebody please email me the URL ?

Thanks,

Richard.

To determine the legality of scanners in your state, trust the opinion of your local law enforcement. What you have here are opinions. I won't pay for the ticket and bail you out of jail! Avoid tricking up the CB beyond stock, contrary to the opinions you read here-again, they don't have to pay your bills, and keep the coax removed from the gps wiring.

Paul, if you don't have whatever radio peaked up you won't be talking to many people especially with the high skip levels now. A radio tuned up to 30-50 watts is a good road machine you need the umph to get over the noise levels not to mention holding your own on the air. Drive around in your dads car and listen. Then ask what the better sounding radio are the antenna, mic power levels etc. most will be happy to talk about their rigs.

You may try a search for scanners radio I believe there were some that had postings of laws. You can also try the rec.radio.scanner NG as well.

A local guy brought in a 1KW X-Force base amp to the shop that I go to. It was almost new and has smoked in short time. The tech said that the amp builder had used hot glue to place components, overall used cheap components and had the thing running at 20+ volts- this was a 12 volt box. The amp was back in the shop a week later to have the keying circuit replaced. The tech said that the X-Force looked about the same as the Armadillo boxes.

712 S.E. Texas.

Michael,

The MRF492 specs are as follows for 14-30 mhz service:

Single device/130 watts RMS out @ 4 watts input, 12V*.....
X 2 = 260 watts RMS,...@ 8 watts input.......

* = 12.5 - 13.6 VDC

Jack

>>>Beaker,
Unlike you, I am not a true radio dork. I only use the radio when on a road trip heading out west to go hunting. It comes in very handy and I meet a lot of great folks on the road that I otherwise would not talk with. I didn't ask about a "better antenna." Pull your head out of your ass and get with the program. It's people like you in these newsgroups that turn people away from a hobby that you obviously like. I realize that I didn't get the "best antenna money could buy" I got an antenna that would meet my needs. You obviously can't answer my questions clearly and in an educated manner when it comes to CBs, but I extend the offer to you that if you have a question about hunting or fishing, MY area of expertise, I would be glad to give my opinion and share my knowledge. "beaker"<<<

with a crappy 3' antenna , it don't matter where you put it . it won't make that much of a difference .

and if "people like me" turn newbies away from CB good . its newbies like you the sit and hassel truckers , or play music . or play with a 10$ eco mic for 45 minutes .

so if i discourage you from getting any ferther intrested in CB , good .

Thanks for your feed back Ron, its very helpful. At this point, it looks like I will get something in the Ranger or possible President line from exportradio.com with one of their super tune up jobs on it. Leaning toward the new Ranger cb model TR966 for $219.99 or the President Grant Export model for $289.99. Prices include "turbo tune" on both. I only need to use the 11 meter band. It will be used on a Wilson 1000 mag mount antenna btw if that matters. Comments? Recomendations?

Nick

At a San Francisco funeral parlor the wakes for three gay men were being held simultaneously. Their 'mates' happened to be at the funeral parlor at the same time, and were discussing what they planned to do with the ashes once their loved ones had been cremated.

The first man said, "My Benny loved to fly, so I'm going up in a plane and scatter his ashes in the sky."

The second man said, "My Carl was a good fisherman, so I'm going to scatter his ashes in our favorite lake."

The third man said, "My Jim was such a good lover, I think I'm going to dump his ashes in a pot of hot chili, so he can tear my ass up just one more time."

And you're still wrong. There is no likelihood that 18 feet of
coax will improve the SWR reading at the radio or eliminate any

of the effects of common mode currents.

If you get higher SWR readings at higher power, you have a problem.
The ratio should stay the same, IF all is well.
I get the same reading at 5 watts, as I do at 1500 watts.

You didn't answer the question. I'll rephrase it if it makes you happy.

Show me where the books say 1/2 wavelength of coax connected
to your radio will "reduce the effects" of common mode currents.

You're not going to find it.

I believe that varying the coax length on a system with common mode currents will affect the SWR reading. I don't believe that 18 feet of coax is any guarantee of an improved reading or improved performance. You have a 50:50 chance of an SWR improvement -- the same odds you get at cutting the coax to any other arbitrary length. It will either get better or it will get worse; there is no guarantee which.

> In doing so it changes the
> load that the radio is terminated in. I have explained this before.

Again, no substantiation.

> At eighteen feet the voltage curve of these currents drop to zero.

This has no basis in fact.

> This zeroing can be termed nulling the
> cable. Nulling the cable decreases the negative effects of coax
> currents.

There are ways to reduce/eliminate negative effects of common mode currents. A balun is one method. 18 feet of coax is a non-method. There is simply no guarantee or likelihood that it will do anything for you.

That's the point???!!! The "point" contradicts your claims.

The radio doesn't need a good RF ground. Whether or not it
is grounded is arbitrary.

The point is that common mode currents at the radio are unpredictable.
Thus, you cannot add any particular length of coax and suddenly know
what they are (as you claim).

Probably a silly suggestion. Why not use the vertical spreader
of the centre element as the top mast section?

Extend the spreader downwards and mount to the mast as usual.

Col

It is just as likely to create a higher reading as it is to create a lower reading. The length is arbitrary.

All your ratchet-jawing and you still haven't provided any substantive reasoning why 18 feet of coax is good. You say it creates a "voltage null at the radio" (which, by the way, is false) but cannot explain how it creates the null or why that is good.

There are just as many conditions where it will couple the radio to a higher than wanted SWR reading. The length is arbitrary.

All your ratchet-jawing and you still haven't provided any substantive reasoning why 18 feet of coax is good. You say it creates a "voltage null at the radio" (which, by the way, is false) but cannot explain how it creates the null or why that is good.

1. I think .15 is optimum but there ain't a lot of diff with smaller ones. This appears to be a first project and a lot of guys hang them on TV towers with TV rotors. Just trying to save the guy some grief. No disagreement with your point but there are other ways to increase the already pretty broad bandwith of a quad.

2. Having lived in ice areas I have seen a lot of quads survive and a whole lot that did not. You might want to expand on how you did it for the gentleman's benefit. Keeping the antenna wire from rubbing or twisting in the same spot with each wind gust is one of the tricks; what might yours be?? What was your pet fix when the wire stretched and the whole thing started to look a bit sad??

3. I probably could have been a bit more adamant about the diamond configuration -- I agree with you entirely -- but a quad fed to be horizontal is definitely horizontal and it seemed he should know that. A lot of times people are amazed that a quad is no better than a yagi for contact with vertically polarized mobiles. For all we know, he lives somewhere where that is possible and for all we know his aim includes working mobiles (in which case the side feed is the way to go, agreed, if this is the only purpose)

Yes, some monumental quads have been built. If the legend that the quad was invented by an engineer for HCJB is true then the first one was built for 31 meters and that is monumental enough. I don't think either this one or a 42 foot boom is appropriate for a beginner's project. I rather doubt that someone asking for the formula has the tower/rotor in place to swing a monster nor the gin pole to install it. So it seemed the KISS theory was appropriate here; whether it is on a 4 or six foot boom is not of major consequence. Just trying to keep the torque moment on the rotor within bounds.

Loops can also be in a Delta configuration and matched to 50 ohms directly via a gamma match or for that matter laid horizontally in a SkyWire setup (get it high). Loops are fun. When the spots are down, a rectangular loop (sides twice as long as the top and bottom) hung from the top of a 2-story is an admirable way to gas with the locals on 10 /11 meters at not a lot of cost and without hanging more aluminum. That is more the fun of the game, to me at least.

If we haven't confuse hell out of the original asker, I will be plenty surprised.

Dick

Hello Jack

I was looking into the feasability of constructing a two
element quad to go inside the ceiling space of my rented
house. A couple of questions if I may.

What would be the best arrangement for two elements,
driven and reflector or driven and director?

If the single quad impedence is 100 ohm and adding elements
lowers it, what would be the feedpoint impedence for two
elements?

I have about 6 feet from ceiling to peak in the ceiling space
so I was going to construct a wire yagi. Richard mentioned a
"diamond shaped" quad which might get me out of trouble if I
shorten the vertical spreader and lengthen the horizontal one.
What effect would this arrangement have compared to a
"square" quad"?

Sorry if all this has been covered before, I am just getting back
into CB after an absence of 20 years and it takes a while to

get back into the swing of things.

blutarsky with kraco trasmiter and bc348 recever. 4 watts. plenty oif dx. if yoiu want dx yoiu are advise to replace antena sytem. blutarsky can give knowlege of good groubnd sytem and vertical rasditior with gain. also capactor for tuneing.

greeting to youi cd is out. yoiu are blutarsky bueatiful negro freind.
plaese the groubnd sytem use iron bed frame buried in yard link to
groubd wire. urtintate is imnportant. smal children or amninals is best.
this is realy works more so than salt.

Not much you really NEED sinks and availiable power supply.I am no engineer
but I would say 35 and the thing would run hot as heck.

So that gives them the right to just use them?

How hard is this, if you are not suppost be on using the frequencies,
stay the hell off. It's that simple.

Whats the matter jack,
don't like the truth?

what about all the equipment you swiped when
you left the roadrunner cb shop?

What about all the other folks you ripped off?

You can't avoid it.

Besides, a little FOI filing can reveal much
about your IRS records (not that I've done so,
but it can be done).

Sorry, request denied. pay me and I'll go away.
Otherwise, you'll have tp put up with me (and all the others
that you have ripped off over the years).

Sorry Eric, You go away. How about letting
you're ISP know about this, off subject and
nothing to do with cb.
For the past 7 years, you haven't changed,
you still come out here crying. Well things have
changed, you either start posting cb related
articles or your ISP I'm sure is going to hear
about how your wasting the bandwidth with
your personal love affair with Jack.

The Landshark
Good Bye, Good Luck, Get Lost!

Thats what happens when you are selling a product that has been copied from someone else ... You don't understand how or why they work they way they do . you are then just a parts assembler

I heard some people local to me were busted by the f.c.c.
Is there a url that I can easily find c.b./ham busting info.(who and what for?)
I tried the fcc webpage, but it seems like trying to find a needle in a haystack.
Maybe an individual provides this service on his webpage maybe.

Hmmmm... some late breaking news....

FCC TURNS DOWN CB DX PETITION

The FCC has denied a petition that would have amended the FCC's Part 95 rules to permit DXing on the 11-meter Citizens Band. The petition sought to amend 95.413 of the rules that prohibits communications or attempts to communicate with CB stations more than 250 km away and to contact stations in other countries.

Designated RM-9807, the petition was filed by Popular Communications Contributing Editor Alan Dixon, N3HOE.

"Dixon's request is inconsistent with the purpose of the CB Radio Service and could fundamentally alter the nature of the service," the FCC said in turning town the petition.

The FCC action was adopted August 18. The Order was released August 21.

The FCC said CB operators generally supported the proposal and stated that the present rule was unenforceable.

The National Association of Broadcasters opposed Dixon's petition. The NAB said that the restriction was necessary to deter CBers from operating at excessive power levels and that consumers must be protected from illegal CB transmissions that interfere with radio, TV and other consumer electronics.

Ranger RCI 2950. Has mods: opened up freq tx/rx, pc board has improved mounting (prevents problems from vibration) ,button on side of radio plays sound toy "south park" sound bite or you can record on it (module inside has input jack, it was with the radio no instructions) Last but not least it has Talkback. Comes with Shure 404b mic (heavy duty) Radio is in good working condition and looks very good . Comes with extra speaker and Swr meter.heavy duty antenna bracket, some coax. mounting bracket, pwr cord. I used this for trucking and no longer drive. Great deal for someone looking for a good radio. $175 plus $9.00shipping/ins. Paypal or money order. email if interested. atinnell_2000@yahoo.com

Another knee-jerk reaction from the clowns that be in DC instead of a well thought out compromise and intelligent decision. J corp and Clearchannel broadcasting are the ones lobbying against any more "permissiveness" on the cb bands. What they are truly afraid of, they will never admit. Just one more reason to turn off the canned bullshit and programming they pipe to commercial stations. Support your local pirate radio!

I got hold of a 30 watter about the size of a pack of smokes. Came from D&R (now Pacific Sales) electronics in Ontario, Cal. Guy said he paid 29.99 for it. It's a piece of trash. Never worked properly at all that is why the guy gave it to me for a Grouper. I've talked to others that had this garbage and none of them did what they said they would.

I know of one that has smoked 4 times and still does not work right. The man who has it is almost afraid to key it now thinking it will blow up again. The first time it smoked it burned 5 output transistors and several resistors. The builder so called repaired it and charged $155. and it was only 3 weeks old. The builder has had it back and forth so much now the case is all out of shape from shipping.It was a 412 base unit. Glad I don't have one.

JR,

I think that has already been indirectly covered.
Most garden variety swr meters are voltage measuring
devices, not a true "reflectometer" such as the Bird.

Being as such, certain precautions must be taken to
avoid the obvious inaccuracies. I hope this answers
your question.

The statement was "never test SWR with an amplifier operating", but if
you keep the power level such that the meter can be calibrated, it should
read the SWR OK (the SWR meter doesn't know if the source of RF is the
transmitter or the amp). Now if you use a high enough output from the amp
(the same goes for the transmitter) that meter cannot be calibrated, then
it should be obvious to the most casual observer that the SWR reading
will be inaccurate.

> True if you use a bird meter but most cbers dont have one

Neither do I at this time. I'm using an MFJ model 870, and at times a
discontinued RS digital meter. Neither shows any variance with power
level changes.
I know that when I started, I had no idea what a decent meter was, much
less a bird.
But them DOSYs looked good!!!!!!

From: Reuben <ruby@cloud9.net>
Message-ID: <sqgfe1a9t9156@corp.supernews.com>
Source record: 49930

Can a Cobra 2010 get the same modifications as the Cobra 2000GTL? Like Channels to 108, watt output control, slider, etc....????? The 200 is a classic, however I don't know about the 2010. How does it stand up to the 2000GTL?

Thanks,
Reuben

I am remote mounting (Trunk) an Amp. Nine feet of coax will not reach. Should I go 12' or 18'? I just want the radio to "see" a lower swr. Is the multiple of 3' the real deal with amps? Also I am going to run about 3' from Amp to Antenna. Is that ok? What gauge wire should I run to Amp (Draws 40 Amp on peaks) with a 12'-15' run? I don't want to small or overkill in wire gauge!

Message-ID: <wLYp5.1863$xL6.83585@news3.voicenet.com>
Source record: 49939

I and many prefer 6' multiples of coax so 6,12,18 etc would work fine..I would use 6' min for the antenna but i like to use 1/4 and 1/2 wave multiples of coax For power to amp 6 guage wire would be more than adequate and not overkill. You can run just 1- 6 guage wire from the battery the "positive connection" to the amp and the ground for the amp you can get from the "chassis" close to the amp with the same guage wire if your putting it in trunk this should be no problem

What ever will reach is the "right length". If the amp's input circuit
is not right, different lengths may vary the readings. Put an SWR meter
on the input and a watt meter on the output and see what happens with
other lengths of coax.

I would run 4 gauge from the battery to the trunk as a minimum, but would
not rule out #2 or bigger. The price difference at Home Depot is a non-issue.
You would be amazed at the voltage drop at 12 volts, having seen first hand
the half-volt drop through 6 feet of #6 feeding a 667!!!

I see your other post about a DX-500. A DX-667 is the same box with a built-in driver. After beefing up the power circuits, you will need a high current alternator. Try putting a MOD-V in front of the DX-500 and then turn the RF power all the down on the 2950. For now, just crank your 2950 up for more drive (and less audio). A 2950 screams on low power.

Source record: 49948

Big Dog,
The 'correct' length of coax to run between radio and amplifier
is just enough to reach, plus anothe 2 or 3 feet for convenience.
The length from the amplifier to antenna should be as short as
possible, within reason.
There is no such thing as 'over kill' when running DC power leads
to remote locations. Welding lead is good because of the large
number of small wires making up the cable. Making a good bonded
connection to the fram/body will do for the ground.
'Doc

> through the system. Can you elaborate on this?

I've found the same thing. Most common SWR meters actually
compare voltages. If the antenna system is correctly tuned
and matched, the ratio of forward and reverse voltages are the
same for all power levels, and the SWR is the same. If there
is a mismatch in the antenna system, then the two voltages can
and do change ratios, making the SWR change.
Probably the most common reason for a change in SWR between
barefoot radio and an amplifier is that the two output impedances
are not the same.

While a Bird watt meter is 'nice', they are no longer
the 'standard' as they once were. There are a lot of
meters just as accurate, and much cheaper. The Bird is
a VSWR meter just as most of the others are.

> maskedmarvel@mindspring.com

Damien,
It doesn't hurt to re-calibrate between channel changes,
but it's certainly not necessary. The difference between
channel-1 and channel-40 isn't really enough to effect the
SWR reading much. Probably less than the accuracy of the
meter.

3442. Re: CB DX

Newsgroup: rec.radio.cb
Date: 2000-08-26 00:00:00 UTC
From: Jay in the Mojave <jay123a@qnet.com>
Message-ID: <39A8676C.40580FB6@qnet.com>
Source record: 49952

Hello TR: Reciting the rules for CB is like waving a red lantern at a run away train. A lot of of guys do it, maybe it makes em feel better?

The CB Radio Service was put on a rich skip talkin HF Band. The CB Radio manufactures started to put S-meters in the radios, larger beam antennas where made available, linear amps came up from the pages of QST, D104 mic's showed up. Ham Radio is unfriendly and geek like, this spurred the large growth of CB radio.

Clubs formed up, and took hold. A friendly informal communication service was an attraction to the common citizen.

I believe the FCC made the CB Band as a back up form to gather technical interest in the mass's knowing that after CW practice people just naturally started to recite rules and regulations. The Government needed a shot in the arm to get the high tech ball rolling. Isn't the time CB Radio was started, that the Soviets put Sputnik into orbit? And I keep hearing Astronauts say "Roger that" on TV a lot.

I'd keep your red lantern polished off.

Jay at jay123a@qnet.com .....In the Great Mojave Desert, just down the road ah ways from the fillin station.

DOES ANYONE HAVE EXPERIENCE WITH THESE AMPS? HOW WELL DO THEY WORK AND ARE THEY WELL CONSTRUCTED?

Jack,
like it or not, you have been confronted with the truth.
now, either you can pay me, or you can put up with me
(and the consequences of your business dying as a result).

Either way, the truth is well known.

You cannot hide any longer. I know where you live and I even have
the physical address of your so-called CB shop. I might just send a
process server there (that would sure cheese off the owner, now
wouldn't it?).

You owe: $150.00 plus collections fees (ammounting to over $1,290
and change) plus any applicable interest I just to apply. GET IT?

I am quite sure the FCC would love to deal with you about your
"character". I am also sure they would be very interested in the fact that
you
work on radios WITHOUT proper license (gen. cl;ass radio/telephone
Commercial Lic.). I am also sure they would be very interested in your
activities regarding CB radio service in general. Also, the IRS would be
very interested in your finances. and then, there is the DEA for your other
various activities (I have tapes, jack, lots of them showing you advertising
drugs
over the air here in the phoenix area).

So, Mr. 228, a.k.a 292, a.k.a Jack Thurston. You cannot hide.
Too many people know about you.

so, PAY ME.

I am not aware of it. CD says he has one. I have a question. For
those of us with 5 watt HTs, we know the HT will become warm (not hot,
of course) with considerable transmission time. How much power could
one run when the total size of the amp is similar to a pack of
cigarettes?

Hello,
I was told to ask you this question so I am sending it to you now.This was copied from my origanal post.Thanks in advance Mike

I was wondering if I bought a leece neville 250 amp alternator and get it mounted,how can I get the thing to run.I want to leave my old alternator on the car then run a battery in the trunk.How will I hook this up.I need a battery and a voltage regulator right.I want to run a Texas Star Mod V and a DX-1600 (Sweet Sixteen).What would I need also how would I set it up all the way from the alternator to the battery. later and thanks in advance mike

Richard,

#1 Typical element spacing for a quad is .15 - .20
wavelength spacing. At 27 mhz that works out to:

#1 wavelength = 1005/27mhz, = 37.2222 feet
37.2222 X .15 = 5.58 feet
37.2222 X .20 = 7.44 feet

#2 the quad can be very stout mechanically, if properly
constructed. I have used a V Quad in high wind areas
here in arizona and never lost one yet.

#3 I strongly suggest that the next time it rains and you
can find a quad in the area somewhere that you pay close
attention as to what the drops of water do on the wire
in the two configurations. In the "X" configuration the
droplets hang from the wires. In parts of the country
that experience icing, this is exzctly the configuration
that you don't want to use! In the "+" configuration the
water runs of the ends of the wires, thus preventing
heavy icing. The X configuration is the one to stay away
from to avoid mechanical problems.

And that's the way it is....

Message-ID: <8o7m8r$l72$1@nnrp1.deja.com>
Source record: 49861

Richard,

#1 Typical element spacing for a quad is .15 - .20
wavelength spacing. At 27 mhz that works out to:

#1 wavelength = 1005/27mhz, = 37.2222 feet
37.2222 X .15 = 5.58 feet
37.2222 X .20 = 7.44 feet

Example: Lightning makes an 8 element quad on a 42 foot
boom. 42/8 = 5.25 feet. This is closer to .14 wavelength,
(Wider element spacings make for broader bandwidth)

#2 the quad can be very stout mechanically, if properly
constructed. I have used a V Quad in high wind areas
here in arizona and never lost one yet.

#3 I strongly suggest that the next time it rains and you
can find a quad in the area somewhere that you pay close
attention as to what the drops of water do on the wire
in the two configurations. In the "X" configuration the
droplets hang from the wires. In parts of the country
that experience icing, this is exactly the configuration
that you don't want to use! In the "+" configuration the
water runs of the ends of the wires, thus preventing
heavy icing. The X configuration is the one to stay away
from to avoid mechanical problems.

And that's the way it is....

Damien,

Also, remember to always use the least amount of transmitter
power necessary to obtain your set meter reading, or calibration.
Never test SWR with an amplifier operating. All you'll get is
higher than normal readings. They are meaningless.

6 Gauge is pushing it, I would use 4 gauge also if you want to use the chassis for a ground you need to upgrade the ground wire from the battery to the chassis and also the wire from the alternator to the battery. Make sure you fuse the wire, I would use a 100 amp fuse. I might get flamed but this is the best way to do it.

Source record: 49980

Howso? 8 guage is plenty enough to hold a 40 amp peak current. 6 would
do it nicely.

Per the stated requirements, 40 amps, 10 would get warm, and might
drop half a volt or so, 8 would handle it, and 6 would do nicely.

I don't know the type of amp from the post, nor what it will really
draw. I've drawn 35 amps thru 10 guage over 10 feet with no drop in
voltage.

Note, also, I did say the bigger the better, for power.

So what's "not so smart" here?

ok Mr. landshark. I gotta question for you:
What is wrong with getting a little consideration or justice?

You wouldn't make such comments if you'd been ripped off.

As for my habits over the last 7 years, that is irrelivant.
and as for this being off topic: when it comes to cb radio,
this isn't. Mr. Thurston works on cb radios without
proper license from the FCC (his "ham ticket" is not
sufficient for work on part 95 gear), and he has sold
(and continues to sell) equipment that is considered illegal
for class D use (such as modified radios, amplifiers, etc).

His technical advice is questionable at best.

As for some other comments regarding his character,
I'll leave that to others that have already stated their case.

Go right ahead and write my ISP. I've already had contact
with them (via phone) on this matter.

Now, I may not be using the best judgement when dealing
with the "jack thurston" matter, but when you have no cash
to pursue other, less public, means, then ..... (you get the picture)

Now, I have a problem with Mr. Thurston, and I would rather
he not get the chance to rip others off as he has done me
(and dozens of others in Phoenix).

This may not be directly on topic, but is is on topic enough
that I haven't recieved any nasty e-mails from others in here.

What say the rest of you? Should a person of ill repute be
allowed to carry on his activities on an unsuspecting CB
public or not?

I agree that SWR meters can be either a voltage ~or~ a current
sensing
meter, but, not both at the same time. At least not in any of the
common
SWR meters on the market.
I also agree that because of harmonics ~and~ parasitics the meter,
which
is not frequency dependant, can certainly show a high SWR. With
properly
designed and constructed amplifiers there shouldn't be any harmonics
or
parasitics though.
If the output impedance of an amplifier or radio is 75 ohms instead
of
50 ohms, for example. And the antenna system's impedance is 50 ohms,
then
the resulting SWR is going to be at or very near 1.5:1. If the output
impedance of the radio or amplifier is 50 ohms and the antenna system
is
50 ohms, the SWR is then 1.0:1, or very close, isn't it? Of course
impedance can affect the SWR readings.

> Measure the SWR at the output of the amp, and there should not be any
> change, no matter whether the amp is in line or bypassed.

An SWR meter between radio and amplifier will measure the SWR that
the radio 'see', looking into the amplifier. Ideally, there should
be
1.0:1 SWR.
An SWR meter between the amplifier and antenna will measure the
SWR
that the amplifier 'see' looking into the antenna. That should
ideally
be 1.0:1 also. This assumes the amplifier is on. If it isn't, then
the radio should still see an ideal SWR through the bypass line.
That's
what will happen if all impedances match, and the amplifier is
properly
designed and constructed. If the impedance of the output of the
radio,
the input impedance of the amplifier, the output impedance of the
amplifier,
and the impedances of the feedline and antenna are all the same (as
they
~should~ be), then you have a 'matched' system, the SWR is at or
near
1.0:1. So in this way, yes, comparing impedances (hence SWR) does

have
meaning.
Who said anything about measuring the SWR between the radio and
amplifier
anyway?

The Houston PD deals with this differently. They broadcast the request
for the tow directly over the PD channels to the tow truck. The drivers
listen on the scanner and the first guy there gets the call. The
dispatcher then cancels the request.

The question I keep asking (but no one has answered) is just *how* did
the police determine it was a scanner? I'm assuming that police are like
the general public and wouldn't know a 2 meter handheld from a PopTart.

Is this like the people who grow pot, TELL everyone they are growing pot
in the hopes of getting arrested and making a case out of it?

I mean, did the guy want to make a case out of this or was he just an
idiot who told the policeman, "look at my shiny new handheld, it can
even pick up police signals"?

3481. cobra 2000 glt freq counter/clock troubles

Newsgroup: rec.radio.cb
Date: 2000-08-27 00:00:00 UTC
From: Wendy Belisle <wbelisle@speedchoice.com>
Message-ID: <sqi7rndgt91137@corp.supernews.com>
Source record: 49997

I received a cobra 2000 gtl for very cheap.... the catch is it does not work. I've fixed all the "issues" except this final one. Here is the problem..... With the power on to the unit (i.e. able to transmit etc) and I set the clock... the time stays just fine.... If I then hit the power button,,, clock resets to 12:00 (kinda like my VCR !!!)

So I figure that there must be a constant power lead to hold up the clock. So I look at the power switch circuit board and behold there appears to be a couple of wires missing.... (solder pads with huge amounts of solder and cut wires!!) I was hoping that someone could take a look at another one and help me out.

Or if any one has any other ideas.....

Thanks in advance

just in case your interested the "issues" were as follows

1. connex echo board mis-mounted thus it shorted a few parts on that... r+r all damaged parts
2. all lights out ,,, r+r light circuit.
3. Receive very low. Corrected Preamp transistor
4. volume control missing. Re- built the connections.
5. poorly engineered channel conversion. rewired and moved switch
6. power caps DOA.... r+r caps
7. general cleaning and polishing...

I was approached once for this in the Steak 'N Shake parking lot in Valpo (the officer heard the radio in my car). I told him that he had the choice of arresting me (I wouldn't sign a citation, if one was written) and having this go through court, or of spreading the word that ham radio operators are legal.

Actually, they have respect for hams, at least in that area (especially during tornado season), but it turns out that most ISP officers are under the impression that hams are required by law to have our calls on our vehicles. Seeing a Camaro with an unusual antenna (I use a Metz), no callsign displayed, and hearing what sounded like police traffic (it was actually Civil Air Patrol) got his suspicions up.

This led to a 10-minute lecture for he and some of his buddies on amateur radio, and how to tell the difference between a ham antenna and a CB or scanner antenna -- and on the different series of callsign (their eyes glazed over for a bit when I explained that not all calls start with W or K, and how many different callsign formats there are).

The word DID get around, I guess -- ISP guys I don't even know wave at me all along that stretch of road.

That is NOT illegal!!
The key word here is the word "incidently".
This is an AMATEUR RADIO that INCIDENTLY recieves police signals.
Scanners are NOT protected!!!!!!!!!!!!!
Amateur Radio's in the possesion of a licensed Amateur's ARE.
And whether it is or is not considered a scanner or is an AMATEUR
RADIO is also up to the FCC not the local hicks!

Hello TR: NO don't goin grabbin any women folk like that there.

U got to have cooth and cunning, be devenare and look good.

When ever we a have ah big CB Break, and everyone gets all liquored up I always try to dance ah few dances, and look good for the ladies.

Now here's some good pointers:
1 T-Bone Sally old man is in prison, so T-Bone Sally is kind of lookin fer ah temporary man. But Bone Crusher Bob will be out of prison in ah few months, so its wise to just let Sally go her own way. Now Welfare Clare old man is on death row, so she has be ah datin a little.

2 Don't get all liquored up at first, some guys can't make it to the door when they arrive, this is all wrong. Ya's need to slowly get all tanked up, with the crown, that way U don't have no drinkin problem, U can always say the crown got all tanked up.

3 Now all the young bucks will try to gettin to know all the ladies at the very first hour, this another wrong way of doin things. Ya simmer over after an hour or so, and politely introduce yours self, I tell em my handle first, then asks if they R ah needin any linear amp repairs, or radio installin. Remember CB linears are always ah breakin down, so even if the amps are workin they ah goin to needin a repair soon.

And I got welfare Checks I ain't spent yet! When ya say this make sure your ball cap is on straight.

4 I give ol Clearwater a few bucks for ah lettin me talkin on the PA (thats publik address system. speakers all over) I tell em all that what a pleasure it is to be tonight, and that I got a Pride DX-300 amp 4-sale, this will spark interests.

5 As the CB Break is ah goinn on, ask some of the older grandma type ladies to dance, this is a gentlemen thing to do, and shows your a good egg. This gets a few of the eye's of the others on ya.

6 Never speak with a full mouth of chaw, and spit in front of the ladies.

7 Never cash your welfare check at the bar, do it in the business office.

8 AS the night travels on, there always be a few who want to draw attention to them selves by comin over the PA System from the radios and big amps out in the parkin lot. This is a good time for dancin with the guys in the parkin lot girl friend.

9 Don't tell em your a ham radio operator, thell think you want em to
have babies and get fat, and hear morse code all day long.

10 Always be a gentleman.

Hope this helps ya out there TR. By the way what channel do you monitor?

Jay in the Great Mojave Desert, ... just down the road ah ways from the
fillin station.

Hey Big Dog, I bet right now your wondering "how the hell should I know if its designed properly?" I try not to get involved in posts about coax lengths, who's amps are the best or if any of this shit is legal. Emails tend to avoid the silly stuff that happends in here. Guys that know will email you. If you haven't been helped by email yet let me know.

3493. Re: N9VKS: Indiana ham arrested for having a scanner

Newsgroup: rec.radio.cb
Date: 2000-08-27 00:00:00 UTC
From: W9SUN <w9sun@qsl.net>
Message-ID: <8obabh$5l5$1@dagobah.blueriver.net>
Source record: 50009
Cross-posted to: rec.radio.amateur.misc,rec.radio.cb,rec.radio.scanner,rec.radio.shortwave

Hello everyone, I just seen this post about this particular ham being arrested for having a police scanner in his automobile. Considering that I live in Indiana and go under the call of W9SUN which is my FCC assigned call sign for usage in the amateur service, I would like to make a few comments. I have read the law from the state of Indiana regarding possession of a scanner. It is not illegal for an amateur radio operator to possess a scanner in the state of Indiana and use it in a mobile setting. The key to this is that state law says that an amateur operator who has been granted a license from the Federal Communication Commission can possess one as long as they are a current FCC licensee. As for myself, I often carry a scanner with me whereever I go just for the hell of it. Anyone in Indiana can have a scanner in their house but in a car is a different story. For you to be able to activate a scanner in a car you must have either approval according to state law or something like being an Amateur Radio operator. So I think what this really comes up to is that either he was doing something else illegal or just a dumbnut officer who didnt know what was going on. Stuff like this needs to be checked out by the ARRL and the FCC and the locals and state officers need to be informed of the laws, not just make arrests based on possession. Its about as silly as being stopped for having an antenna, I guess that maybe they think people are using police radios. It would be that a 2 meter antenna would be very close in frequency to the police bands here locally. Down below I will post the actual law as found in the Indiana Code. So I think that this is either regarding to other illegal activity or just a cop that didnt know his head from his rear. Thanks for your comments.

IC 35-44-3-12
Sec. 12. (a) A person who knowingly or intentionally:
(1) possesses a police radio;
(2) transmits over a frequency assigned for police emergency purposes; or
(3) possesses or uses a police radio:
(A) while committing a crime;
(B) to further the commission of a crime; or
(C) to avoid detection by a law enforcement agency;
commits unlawful use of a police radio, a Class B misdemeanor.
(b) Subsection (a)(1) and (a)(2) do not apply to:
(1) a governmental entity;
(2) a regularly employed law enforcement officer;
(3) a common carrier of persons for hire whose vehicles are used in emergency service;
(4) a public service or utility company whose vehicles are used in emergency service;

---
(5) a person who has written permission from the chief executive
officer of a law enforcement agency to possess a police radio;
(6) a person who holds an amateur radio license issued by the
Federal Communications Commission if the person is not transmitting over a
frequency assigned for police emergency purposes;
(7) a person who uses a police radio only in the person's dwelling
or place of business;
(8) a person:
(A) who is regularly engaged in newsgathering activities;
(B) who is employed by a newspaper qualified to receive legal
advertisements under IC 5-3-1, a wire service, or a licensed commercial or
public radio or television station; and
(C) whose name is furnished by his employer to the chief
executive officer of a law enforcement agency in the county in which the
employer's principal office is located;
(9) a person engaged in the business of manufacturing or selling
police radios; or
(10) a person who possesses or uses a police radio during the normal
course of the person's lawful business.
(c) As used in this section, "police radio" means a radio that is
capable of sending or receiving signals transmitted on frequencies assigned
by the Federal Communications Commission for police emergency purposes and
that:
(1) can be installed, maintained, or operated in a vehicle; or
(2) can be operated while it is being carried by an individual.
The term does not include a radio designed for use only in a dwelling.
As added by Acts 1977, P.L.342, SEC.1. Amended by P.L.162-1994, SEC.1.

This is true. Everytime I've blown up I can trace it back to something I've done wrong or different. I don't run X-FORCE or any other boxes mentioned in this group. Every box in my Suburban has won it's class at least once. Bottom line is this, if it is not working, What part did you play in it?

:>even pick up police signals"?
:That is NOT illegal!!
:The key word here is the word "incidently".
:This is an AMATEUR RADIO that INCIDENTLY recieves police signals.
:Scanners are NOT protected!!!!!!!!!!!!!
:Amateur Radio's in the possesion of a licensed Amateur's ARE.
:And whether it is or is not considered a scanner or is an AMATEUR
:RADIO is also up to the FCC not the local hicks!

The Indiana Code exempts all radios, to include scanners, if one has a ham license, a GROL license, if one is a police officer, a fire fighter, works for the government, is a news reporter. Total exemption except for being able to transmit. And some agencies, like the one I work for, are allowed to transmit on all police frequencies.

Hello Just a Ham: Yeah this is the very best of ham radio.

We call it the Zoo frequency.

We listen to it all the time over here in the Antelope Valley. Going to the TRW swap meet isn't the same without 435.

We still miss Frank. But it sure is entertaining when norman gets all wound up. And tell Norman that he was a small strap on CB Channel 15 in the old days. Commodore, Buck Shot, Jimmy Cat, Ten Toes, Lindy, Arron, and most the rest just walked all over him. Tell Norman that Jay said that!

Jay in the Great Mojave Desert.

I said it before, I feel this is an appropriate forum to let the world know about rip off dealers and techs. If one person says it, take it with a grain of salt. If two or more chime in and make similar claims, there may be something to it. Whether or not said technician is "licensed" to do whatever work is done should be considered before you deal with him, not after. Lousy hacking on a radio is one thing and it is up to the consumer to do the homework before selecting a technician just like any other situation, IE: mechanic, builder, plumber, painter, electrician, etc. But outright cash ripoffs and merchandise never received should be addressed in whatever legal ways the complainant sees fit. I see no problem with addressing those issues here..if it isn't true and it is malicious slander, the tech has his own recourse.

Keith,

Hello to a fellow Civil Air Patrol member! I almost got stopped in In-
diana near Bluffton. I was aware of the "scanner law" up there, and I
think that was why the guy was following me. I did, however, have my
ham call on the back window. I wasn't speeding, so I can't think of
another reason. In North Carolina, Civil Air Patrol issues specialty
license plates (optional) for members, and I had one of those also. I
saw him talking on the radio as he tailed me and he peeled off after
awhile. I'm sure he was interested in the antennas since I had a 2 meter
and a large HF antenna, too.

BTW, as to thwarting "vulture" wrecker" operators, the local county has
am excellent solution. All county wrecker operators are in the police
database. If the parties involved in the wreck don't specify a parti-
cular wrecker, the county calls a wrecker on a rotational basis. The
computer program moves the companies up the "list". The dispatcher then
calls out the one on top. By rotating them, the local wreckers get
plenty of business, it is fair, and keeps everybody happy.

73

Jerry

>
> 1) Running a RCI-2950, What is the best drive level for this amp?

If the radio has the negative peak compression mod, 2 watts
dead-key. If not, 4 watts dead-key. As for peak drive,
the amp can handle whatever the radio can produce.

> 2) Can I chassis ground negative cable off amp instead of going all the
> way to battery?

Yes, IF there is a very low resistance path back to the
battery that can handle that much current. If in doubt,
return the negative to the battery. A little trick I
recommend is to run the red and black wires to the ends
of the battery cables opposite the battery. That trick
prevents corrosion, clutter around the battery, and it
usually substantially reduces the wire lengths--which
results in a lower voltage drop under load and higher
amplifier output.

> 3) what rms and peak can expect from this amp with a RCI-2950 as driver?

Again, that depends on how the radio is set up and the
under load DC supply voltage at the amp. A Texas Star
500 will generally put out its face value in an average
installation with a 2950 that's had a simple tune-up.
That's 500 peak watts. The RMS (aka average) power
should hold at 1/4 to 1/3 of the peak (unless negative
peak compression was employed) depending on the meter
used to take the reading. That would be 125 to 167
watts.

> --

There is another possibility. There seems to be a growing number of
stations that are transmitting "number messages" (string of numbers)
in and around Chicago. You can hear them on 40 metres and 20 metres
in the CW band. I passed a guy up on the Indiana Toll Way who
overloaded my receiver with a CW number broadcast. He looked like he
was from southern Europe and had ham plates on his car.

If this is true, and you must know that there are a number of state
troopers in intel units, then the cops may be looking at hams as a
cover for spying and terrorism commo. Not a great future for us hams.

Hello everyone, I just seen this post about this particular ham being
arrested for having a police scanner in his automobile. Considering
that I
live in Indiana and go under the call of W9SUN which is my FCC
assigned call
sign for usage in the amateur service, I would like to make a few
comments.
I have read the law from the state of Indiana regarding possession of
a
scanner. It is not illegal for an amateur radio operator to possess a
scanner in the state of Indiana and use it in a mobile setting. The
key to
this is that state law says that an amateur operator who has been
granted a
license from the Federal Communication Commission can possess one as
long as
they are a current FCC licensee. As for myself, I often carry a
scanner with
me whereever I go just for the hell of it. Anyone in Indiana can have
a
scanner in their house but in a car is a different story. For you to
be able
to activate a scanner in a car you must have either approval according
to
state law or something like being an Amateur Radio operator. So I

think what
this really comes up to is that either he was doing something else
illegal
or just a dumbnut officer who didnt know what was going on. Stuff like
this
needs to be checked out by the ARRL and the FCC and the locals and
state
officers need to be informed of the laws, not just make arrests based
on
possession. Its about as silly as being stopped for having an antenna,
I
guess that maybe they think people are using police radios. It would
be that
a 2 meter antenna would be very close in frequency to the police bands
here
locally. Down below I will post the actual law as found in the Indiana
Code.
So I think that this is either regarding to other illegal activity or
just a
cop that didnt know his head from his rear. Thanks for your comments.

IC 35-44-3-12
Sec. 12. (a) A person who knowingly or intentionally:
(1) possesses a police radio;
(2) transmits over a frequency assigned for police emergency
purposes; or
(3) possesses or uses a police radio:
(A) while committing a crime;
(B) to further the commission of a crime; or

(3) a common carrier of persons for hire whose vehicles are
used in
emergency service;
(4) a public service or utility company whose vehicles are
used in
emergency service;

---
(5) a person who has written permission from the chief
executive
officer of a law enforcement agency to possess a police radio;
(6) a person who holds an amateur radio license issued by the
Federal Communications Commission if the person is not transmitting
over a
frequency assigned for police emergency purposes;
(7) a person who uses a police radio only in the person's

dwelling
or place of business;
(8) a person:
(A) who is regularly engaged in newsgathering activities;
(B) who is employed by a newspaper qualified to receive
legal
advertisements under IC 5-3-1, a wire service, or a licensed
commercial or
public radio or television station; and
(C) whose name is furnished by his employer to the chief
executive officer of a law enforcement agency in the county in which
the
employer's principal office is located;
(9) a person engaged in the business of manufacturing or
selling
police radios; or
(10) a person who possesses or uses a police radio during the
normal
course of the person's lawful business.
(c) As used in this section, "police radio" means a radio that is
capable of sending or receiving signals transmitted on frequencies
assigned
by the Federal Communications Commission for police emergency purposes
and
that:
(1) can be installed, maintained, or operated in a vehicle; or
(2) can be operated while it is being carried by an
individual.
The term does not include a radio designed for use only in a dwelling.
As added by Acts 1977, P.L.342, SEC.1. Amended by P.L.162-1994, SEC.1.

Oklahoma Highway Patrol and a special drug taskforce unit routinely stop
cars with extra radio antennas (especially mag mount) along I-35 as part of
their interdiction effort. I-35 is a heavily used route for the northward
flow of drugs and part of the profile is the "escort" vehicle with radios to
"sniff-out" the police and warn the transport vehicle. I've been stopped
and checked several times.

I now have callsign license plates, along with SkyWarn decals. Seems to be
working so far, haven't been pulled over since.

> Should I go 12' or 18'?

It doesn't really matter. Use enough to get from A to B.

> I just want the radio to "see" a lower swr.

Than what? If the input SWR is low, the coax length
won't change it. If the input SWR is high, the amp
needs to be repaired.

> Is
> the multiple of 3' the real deal with amps?

No.

> Also I am going to run about
> 3' from Amp to Antenna. Is that ok?

As long as that's enough to get from A to B.

> What gauge wire should I run to Amp
> (Draws 40 Amp on peaks) with a 12'-15' run?

No smaller than 8.

I'm curious about the amp too. What's a 4-pill cookie with a
3 button Texas Star mod? Why not just have a Texas Star 500.

However, what happens if ham radio is being used as a cover for spying
or terrorism? Or even drug smuggling??
